word 'psychoanalysis' should not mislead us here, because it did not refer to the empirical process of the knowing individual mind, but rather to a collective psychology of knowledge itself. According to Bachelard, the epistemological problem of objective knowledge had to be raised in terms of obstacles. These 'epistemological obstacles' are not external obstacles that impose themselves upon knowledge (such as human fallibility) but are internal to the act of knowing itself, as its necessary inertia. The obstacles against objective knowledge are not simply errors that a progressively more perfect and objective knowledge rectifies, but are one of the conditions of the possibility of objective knowledge itself: indeed, there is no possible knowledge that is not in a dialectic relation with a previous obstacle. Influenced by phenomenology, Bachelard also believed that such a philosophy was insufficient because it was too abstract and it ended up underestimating the material and procedural aspects of objectivity, and thus he spoke of a 'phenomenotechnics' of objective knowledge. There are four main epistemological obstacles that scientific knowledge has to overcome in order to be objective. The first one is common opinion or common sense, with which objective knowledge has to break. The second is the notion of an original and first experience, which culminates in the notion, or better the myth, of the 'given' (equally put into question by postanalytic philosopher Wilfred Sellars) as the natural data upon which objectivity would be built; on the contrary, objective experimental science constructs its results upon nature and sometimes against it. The third major obstacle is the 'realist obstacle,' exemplified by the concept of substance, which is the naive way of conceiving the reality of the world. Bachelard did not advocate relativism, but tried to highlight the fact that reality was a process and that objectivity was a result of a complex interaction between subjects and objects. Finally, there was the 'animist obstacle,' which consisted in attributing magic and self-explanatory power to the concept of life, the valorization of the notion of life and 'the vital' in the pursuit of objective knowledge. Objective knowledge was in this picture the result of a historical process of intellectual catharsis and self-discipline (Bachelard, 2002). The so-called French tradition of epistemological history picked up this idea of procedural objectivity and, purified of its more psychological features, applied it mostly to the analysis of the life sciences and the human sciences.

In the Anglo-American context, the philosophy of Popper has been a transitional step toward more radical epistemological critiques. Popper believes that the problem of objectivity has to be approached from the point of view of that of realism, the simple idea that the world exists independently of the human mind and action. As such, science and knowledge presuppose realism. Popper's theory of the three worlds starts from this assumption. According to it there exist: (1) the world of physical objects and physical states; (2) the world of conscious or mind states; and (3) the world of 'objective contents of thought,' especially scientific and poetic thought. World (1) is the world of everyday objects, like tables and trees; it is objective because other people can experience it, and it is autonomous because their existence is not dependent upon us. World (2) is that of all our psychological experiences, like emotions, memories, and so forth; it is subjective because every such state is different from that of other people, and it is not autonomous, because it depends upon the mind of the humans. World (3) is the world of scientific and more generally intellectual human activity. Other kinds of objects do not fall within these two worlds: words, propositions, laws, symphonies, theories, numbers, and so forth. These are not material objects, but they are nonetheless objective; even if they are produced by the human mind, once created, they produce effects that were not predictable, nor included in the subjective intentions of their producers. Language plays a decisive role in this process, because it makes public, communicable (intersubjective) an object of the private world (2) (Popper, 1972: pp. 153–165).

From this theory derives that there are two kinds of knowledge: subjective and objective. Subjective knowledge is a state of mind or a disposition to behave in certain ways; objective knowledge consists in problem, theories, and argumentations as such. Traditional epistemology is mistaken because it takes scientific knowledge to be an object of world (2), thus focusing on the problem of justification, of how a private state of mind can be considered objective knowledge. Popperian epistemology wants, on the contrary, focus on problems and arguments as such, as a process of conjectures and confutations. Objective knowledge is an ever-evolving natural product of humans, and it grows through this continuous interactions of the world (3) with our subjective world (2) (Popper, 1972: pp. 106–115).

A central feature of this process is a sort of continuous public rational criticism that scientists apply to their production of objective knowledge. Popper rendered more dynamic the traditional problems of metaphysics and epistemology of objectivity, but this conception of rational criticism has been criticized by postanalytic philosophers and historians of science. Starting from the 1950s, the temporal dimension entered the realm of philosophical investigations of objectivity. Kuhn saw it as belonging only to the rare periods of revolution in the science, but inapplicable to the procedures of 'normal science,' while scientists are engaged in conforming previously shared assumptions (Kuhn, 1962). Feyerabend (1975) went beyond Kuhn in fighting every notion of scientific method that would guarantee a more objective knowledge. Imre Lakatos developed a more rationalistic and less relativistic notion of objectivity, embodied in his 'research programs' theory, which wanted to harmonize Popper's fallibilism and the critiques by Kuhn and Feyerabend. According to Lakatos, the development of the history of science is always characterized by the competition of two or more alternative research programs, built around a metaphysical core assumed as preliminary valid and not subject to criticism. Objective knowledge is not a simple process involving nature on the one hand, and scientists on the other, but a more complex one involving the historically changing research programs (Lakatos, 1978).

Some of these issues have been picked up by more recent thinkers (Dworkin, 1996; Nagel, 1997). In particular, these philosophers have raised two kinds of doubts about the preceding kinds of characterizations of objectivity. First, these philosophers question whether the conception of metaphysical objectivity (especially strong metaphysical objectivity) does not presuppose a vantage point on the way things 'really' are to which we can have no access. Second, these philosophers

wonder whether the conception of metaphysical objectivity as mind-independent is not a paradigm too closely tied to a picture of the objectivity of the natural world, and thus either does not make sense or should not be applied with respect to the objectivity of domains like ethics or aesthetics. In these evaluative domains, it makes no sense to ask about whether there are evaluative facts 'out there in the world.' The objectivity of evaluative discourse is simply a matter of its susceptibility to reasons, of our ability to subject ethical positions to rational scrutiny and discussion.

Picking up and putting together the various threads of postanalytic philosophy, someone like Richard Rorty has been able to consider objectivity as a useless, or worse a dangerous, concept, and proposed to substitute alternative notions that include social, or intersubjective, practices. The traditional ideal of objectivity as the true knowledge of what is real in the external world is put into question by denying that a distinction between human interests and practices and knowledge takes place. 'Objectivity' can only be a settlement on the best beliefs and reasons that human beings can give to each other and share, and thus it can only be based on the consensus of the scientific community. Thus Rorty conceives the sciences as aiming toward solidarity rather than metaphysical and epistemological objectivity: scientific knowledge, with its remarkable capacity of prediction and control, is to be praised because it fulfills in the best possible way human interests, not because it attains an objective representation of the mind-independent 'external world.' In other words, objectivity is not transcendent with respect to the human world, but it is given by a pragmatic research for shared and applicable knowledge. Objectivity does not need to be grounded in a transcendent conception of the world and in an epistemology of representation, because objective knowledge is not an enterprise different from other human activities, and as such it is a matter of beliefs, desires, debating, and of what works better. Significantly, Rorty praises the scientific enterprise in terms of the moral virtues of the scientists, aiming at an 'unforced agreement' based on persuasion rather than coercion, on respect for the opinions of others, and on curiosity. By putting into question the fundamental separation between subjective interests and objective representations, some of the traditional epistemological features of objectivity – a notion he ultimately wanted to destroy – became in Rorty's terms a moral and political model of virtues for the human community (Rorty, 1991: pp. 21–34).

Another deeply influential set of epistemological criticisms toward the traditional way of conceiving objectivity comes from feminist epistemology and philosophy of science. Feminist epistemologists deal with how gender influences the processes of the production and justification of knowledge and science, and how the knowing subject, individual and collective, is shaped by gender. Feminist critique of objectivity focuses in particular on three points: (1) the idea of objectivity as absence of perspective, (2) the idea of objectivity as tied to value neutrality, and (3) the idea of metaphysical objectivity as the picture of what is really real on the world independently from the human (gendered) mind. Feminist conceptions of objectivity are thus explicitly pluralistic.

Donna Haraway put into question the very fact that the scientific goal must be a single and unified vision of the world, which has historically been the vision of the dominant groups in a given society. Thus she proposed to substitute 'the god trick of seeing everything from nowhere' with what has been called 'situated knowledge.' In this view, objectivity remains a valuable goal, but it is conceived in different terms: 'objectivity turns out to be about particular and specific embodiment and definitely not about the false vision promising transcendence of all limits;' it follows that only partial – gendered, embodied, socially determined – perspectives promise objective vision. Since the knowing self is limited in every possible way, objectivity cannot be anything else than a communal experience where subjects put together their perspectives without claiming to abolish them (Haraway, 1988).

The emphasis on situated knowledge gave way to a general theory of knowledge called 'standpoint knowledge,' which argues that what happens in social relations both enables and limits, without rigidly determining, what we can know. Sandra Harding in particular has emphasized that a better vision of objectivity must not limit itself to criticize the naive individualism of traditional views, according to which objective knowledge can be attained by overcoming individual biases, but has to put into question the widely cultural assumptions held by scientific communities. Unlike 'weak objectivity,' relying only on an impossible neutrality, Harding proposed a 'strong objectivity' program focused on maximizing objectivity by detecting the values and interests that constitute the scientific projects, and by distinguishing those interests that enlarge from those that limit objectivity. Given the fact that the history of scientific practices and theories is dominated by androcentric values that benefited men, women are most likely to be critical of such values, because they have less to lose. The general conclusion is valid also for Eurocentric and bourgeois values of scientific communities: only by adopting a standpoint different from that of the dominant social groups can objectivity be maximized and more accurate empirical and theoretical accounts of the world provided. And this can in turn be obtained through 'reflexivity,' namely by making explicit all the partial standpoints of knowers and of the community of knowers, thus enhancing objectivity by avoiding a confusion of one's own partial perspective with a comprehensive view, and by highlighting contingencies of representation (Harding, 1995).

In a different but related vein, Helen Longino proposed a notion of objectivity as the result of the democratic life and discussion of a community of knowers, which has to have recognized places of criticism and shared standards, and must be responsive to criticism, with an equally distributed intellectual authority (Longino, 1990).

The Historical Epistemology of Objectivity

'Objectivity' tends to be conceptualized in terms of its opposite, 'subjectivity.' Subjectivity connotes variability and contingency, the perspective of an individual human subject, prey to local circumstances and molded by them into a distorting mirror. Objectivity is, by contrast, the 'view from nowhere,' with no local circumstances – and no perspective – to distort the mirror (Dear, 1992: pp. 619–620). In contemporary philosophy, objectivity has a 'hybrid' character. Lloyd (1995: p. 353) noted that 'objective' can mean detached, disinterested, unbiased,

impersonal, not having a point of view; it also means public, publicly available, observable, or accessible (at least in principle); it means existing independently or separately from us: that which is really existing, Really Real, the way things really are. We can say that the first two meanings are epistemological and the third metaphysical. Historians had already emphasized the fact that objectivity is not a single idea, but rather "a sprawling collection of assumptions, attitudes, aspirations and antipathies" (Novick, 1988: p. 1; Shapin and Schaffer, 1985). In recent years, another approach to objectivity has emerged, which can be placed under the label of historical epistemology, the historical study of the scientific categories, or meta-concepts, that structure our present thoughts and organize our practices, a study that regards the history of concepts, practices, instruments, and 'moral economies' of sciences. The historical epistemology of objectivity is aware and takes into full account the criticism coming from feminist and postanalytic philosophy, and it starts from the fact that "before we can decide whether objectivity exists, and whether it is a good or bad thing, we must first know what objectivity *is* – how it functions in the practices of science" (Daston and Galison, 2007: p. 51). According to this approach, (1) objectivity has to be treated historically; (2) the history of objectivity is the history of the merging of discourses, practices, epistemologies, and moral values; (3) the history of objectivity indicates the existence of a plurality of different epistemic virtues; and (4) contrary to a purely philosophical approach, objectivity must be considered as something different from semantic, epistemological, or metaphysical conceptions of truth.

Among historians of science, Lorraine Daston and Peter Galison gave us the most systematic account of the history of the concept of objectivity. Their core thesis is that the epistemic virtue called objectivity became the dominant scientific norm during the second half of the nineteenth century, through the accumulation and crystallization of a series of heterogeneous elements (such as techniques, instruments, scientific institutions, the birth itself of an international scientific community), and in correspondence with a general change of meaning of the meta-concepts – that is, concepts that organize other concepts – of subjectivity and objectivity. From Kant on, they argue, these two terms underwent a sort of 180-degree inversion and quite quickly took the meaning that we are familiar with: roughly speaking, objectivity designates the matter outside the mind, and subjectivity the mental and inner sphere of thought. For example, in the late Middle Ages, thinkers such as Duns Scotus and William of Ockham (fourteenth century) believed that the meaning of the couple of adjectives *objectivus/subjectivus* was, respectively: things that are present in the mind/things as they are in themselves; traces of this meaning can be found even in Descartes. Since about the second half of nineteenth century, all the principal European dictionaries began to register a meaning very close to ours. The only thing that remains the same in the history of these concepts is the fact that they always are in a relationship of mutual opposition and mutual definition: objective is the nonsubjective, and vice versa.

The history of the epistemic virtues related to objectivity is therefore linked to changing conceptions of subjectivity, which can be distinguished roughly as follows: the rational soul of the seventeenth century; the self as an aggregate of faculties of the eighteenth century; the post-Kantian self as a unity centered around the will of the nineteenth century; and finally, the vertical self, deep and unconscious, of the twentieth century (Daston and Galison, 2007: pp. 29–31). If one wishes to understand the emergence and the importance of objectivity as sets of epistemic virtues and as a scientific meta-concept, then one has to oppose it to the parallel notions of subjectivity. Daston and Galison start from two presuppositions: the self is historically determined; and it is shaped by a series of practices and exercises. In order to answer the question about the emergence of the meta-concept of objectivity one needs to look at the meta-concept of subjectivity, but starting 'from below:' who is the scientific self? The scientific self is anyone who becomes so as a result of the application of particular technologies of the self, deemed necessary to be a scientist. An epistemic virtue is then a melting between ethics and epistemology realized through instruments and technologies of the scientific self, regulated by an ethico-scientific ideal (Daston and Galison, 2007: pp. 198–199).

Daston and Galison take up from Foucault the concept of techniques of the self and they apply it to the formation of the scientific self with special reference to the second half of the nineteenth century and to what they call 'mechanical objectivity.' The techniques of the self corresponding to mechanical objectivity are practices such as the training of the senses in scientific observation, the keeping of laboratory notes, the monitoring of one's hypotheses and opinions, the canalization of one's attention, the control of one's beliefs and fantasies, and the suppression of the spontaneous forms of the will; the scientist applies these techniques to the scientific self and thus obtains, at the very same time, objective results, objective knowledge. In order to capture the peculiarity of nineteenth-century mechanical objectivity, Daston and Galison make a historical comparison with other epistemic virtues, insisting on the fact that every emergence of a new epistemic virtue is not a mere substitution of the existing ones, but rather a reorganization of the field of possible scientific practices and ideals. Among them, they call 'truth-to-nature' the epistemic virtue dominant in the eighteenth century, characterized by the scientist's ability of selecting and synthesizing, grasping and stylizing the essence of natural phenomena; and 'trained judgment,' which emerges in the first years of the twentieth century, a virtue marked by the scientist's use of unconscious intuitions and interpretative techniques about natural phenomena (Daston and Galison, 2007: pp. 42–50).

Observational Studies: Outcome-Based Sampling

Abstract

Samples in observational studies are outcome-based if the probability of being sampled depends on responses that are the subject of study. This may occur inadvertently due to attrition, self-selection, or stratification that is correlated with response, or may result from deliberate design decisions to facilitate observation, as in case-control studies. Outcome-based samples require special attention to issues of robustness that arise because variations in sampling protocol may be confounded with response, and issues of inference that arise because procedures that ignore the selection induced by the sample frame may be statistically inconsistent. This article discusses these issues and outlines some practical methods for consistent estimation of population conditional response probabilities.

Introduction

An outcome-based sample in an observational study is one obtained by stratification on the basis of response behavior whose explanation is the sarget of study. Observations on response and explanatory variables (covariates) are collected within each stratum. These are then used for statistical inference on the conditional distribution of the response, given the covariates. For example, a study of occupational choice may draw a sample stratified by occupation, so the first stratum is a sample of engineers, the second stratum is a sample of educators, and so forth. Data are collected on covariates such as gender and utilization of training subsidies. The observations are then used to infer the impact of training subsidies on occupational choice.

Outcome-based sampling is also termed endogenous, intercept, on-site, experience-based, response-based, or choice-based sampling, and in biostatistics, retrospective or case-control sampling. To illustrate, case-control designs sample from one stratum that has a specified outcome (the cases) and a second stratum that does not (the controls). There may be further stratification of the controls so that they resemble the cases on some covariates such as age. Outcome-based samples can be contrasted with exogenous or prospective samples that sample randomly from the target population, or stratify solely on covariates. Outcome-based sampling methods have had wide application in social science, biostatistics, and engineering; examples are Akin et al. (1998), Domowitz and Sartain (1999), Laitila (1999), and van Etten et al. (1999).

Design and Robustness Issues in Endogenous Samples

Outcome-based samples are useful for studying rare responses that are difficult to observe in random samples of practical size, such as risk factors for a rare disease, and for studying outcomes that randomly sampled subjects are unable or unwilling to report. An example of the second type is the study of mental illness as a risk factor for homelessness, where the only practical sample methodology may be one that surveys cases who are homeless and controls who are not (Early, 1999; Lacy, 1997). Outcome-based sampling may also offer economies in recruiting and interviewing subjects. For example, consumers who purchase and register a product form an outcome-based stratum that the manufacturer can survey inexpensively.

Outcome-based samples may arise by deliberate design, as in case-control studies, but can also be unintentional. General purpose surveys often use cluster sampling to facilitate enumerating and contacting subjects. The cluster stratification is exogenous for most purposes, but has the properties of an outcome-based sample for behavior that is related to the stratification. For example, cluster sampling by census tract or area code becomes outcome based in studies of residential location of migration behavior. Further, screening, self-selection, and attrition create statistical problems like those in outcome-based samples. For example, a sampling protocol that selects subjects by random-digit dialing will over-sample individuals with more than one telephone line, resulting in a sample that is endogenous for study of the demand for telephone service. Differential attrition in which, for example, individuals who live alone are more difficult to contact or more frequently refuse to be interviewed, will produce a sample that is endogenous for the study of living arrangements.

Outcome-based samples are less robust than random samples. Because stratum boundaries coincide with the behavioral categories under study, variations in sampling protocol across strata are confounded with behavioral response. For example, in case-control studies of risk factors for disease, variations in question format between cases and controls, or even the context for questions induced by the disease status, can alter recall on exposure to hazards. Unlike prospective studies where randomization of treatments and double-blind designs can minimize the risks of contamination, retrospective studies are vulnerable to investigator bias and latent causal factors that are correlated with measured risk factors. As a result, differences in reported exposure to risk factors between cases and controls may arise from spurious sampling effects as well as from a true causal effect. The difficulty of avoiding contaminating bias in case-control settings is discussed further in Austin et al. (1994), Feinstein (1979), Lilienfeld and Lilienfeld (1979), and Taubes (1995).

Statistical Inference in Endogenous Samples

Statistical methods developed for random samples will often be inconsistent or inefficient when applied to endogenous samples. The essential problem is that the analysis is attempting to infer properties of the conditional distribution of outcomes given covariates, using observations that are drawn from conditional distribution of covariates given outcomes. The solution to the inference problem is to incorporate the mapping between the conditional distributions in the analysis, either by reweighting observations so that they behave *as if* they were drawn from a random sample, or by reweighting the probability model for a random sample so that it is consistent with the empirical sampling process. The statistical issues in analyzing outcome-based samples were treated in a seminal paper by Manski and Lerman (1977), with further results by Manski and McFadden (1981) and Cosslett (1981). A largely independent treatment of logistic regression in the case-control model appeared in biostatistics, notably in the papers of Anderson (1972) and Prentice and Pyke (1979). Recent papers by Hsieh et al. (1985) and Breslow (1996) sharpen the statistical analysis of case-control designs and show their relationship to the general problem of endogenous sampling.

Table 1 is a contingency table that depicts, schematically, the population probability law for an outcome variable y and a vector of covariates z. (This exposition treats y and z as discrete, but the discussion applies with minor modifications to the case where y and/or some components of z are continuous.) The joint probability of a (y, z) cell can be written as the product of the conditional probability of y given z times the marginal probability of z, $p(y, z) = P(y \mid z) \cdot p(z)$. The row sums give the marginal probability $p(z)$ of z, and the column sums give the marginal probability $q(y) = \sum_z P(y \mid z) \cdot p(z)$ of y. Dividing a cell probability by its column sum gives the conditional probability of z given y, $Q(z \mid y) = P(y \mid z)p(z) / q(y)$. This mapping between conditional probabilities is Bayes' Law. The target of statistical analysis is the conditional probability $P(y \mid z)$, sometimes termed the response probability. In applications, $P(y \mid z)$ is usually assumed to be invariant under treatments that alter the marginal probability of z; then knowledge of $P(y \mid z)$ permits the analysis to forecast y in new populations or under policy treatments where the z distribution is changed. (A conditional probability with this invariance property is sometimes said to define a causal model. It is true that a causal structure will imply this invariance property, but it is also possible for the invariance property to hold, making forecasting possible, without the presence of a deeper causal structure. Further, there are straightforward statistical tests for the invariance property, while detection of true causal structures is beyond the reach of statistics. For these reasons, it is best to avoid the language of causality and concentrate instead on invariance properties.)

Table 1

	y_1	y_2	…	y_J	
z_1	$P(y_1 \mid z_1, \beta_0)p(z_1)$	$P(y_2 \mid z_1, \beta_0)p(z_1)$	…	$P(y_J \mid z_1, \beta_0)p(z_1)$	$p(z_1)$
z_2	$P(y_1 \mid z_2, \beta_0)p(z_2)$	$P(y_2 \mid z_2, \beta_0)p(z_2)$	…	$P(y_J \mid z_2, \beta_0)p(z_2)$	$p(z_2)$
:	:	:		:	:
z_K	$P(y_1 \mid z_K, \beta_0)p(z_K)$	$P(y_2 \mid z_K, \beta_0)p(z_K)$	…	$P(y_J \mid z_K, \beta_0)p(z_K)$	$p(z_K)$
	$q(y_1)$	$q(y_2)$	…	$q(y_1)$	1

Random sampling draws from the table in proportion to the cell probabilities. Exogenous stratification draws rows, with probabilities that may differ from the population marginal probabilities $p(z)$, and then within a row draws columns in proportion to their population conditional probabilities $P(y \mid z)$. A simple outcome-based sampling design draws columns, with probabilities that may differ from the population marginal probabilities $q(y)$, then within a column draws rows in proportion to their conditional probabilities $Q(z \mid y) = P(y \mid z)p(z) / q(y)$.

More complex endogenous sampling designs are also possible. A general framework that permits a unified analysis of many sampling schemes characterizes the sampling protocol for a stratum s in terms of a probability $R(y, z, s)$ that a member of the population in cell (y, z) will qualify for the stratum. The joint probability that a member of the population is in cell (y, z) and will qualify for stratum s is then $R(z, y, s) \cdot P(y \mid z, \beta_0) \cdot p(z)$. Then the proportion of the population qualifying into the stratum, or qualification factor, is $r(s) = \sum_z \sum_y R(z, y, s) \cdot P(y \mid z) \cdot p(z)$, and the conditional distribution of (z, y) given qualification is $R(z, y, s) \cdot P(y \mid z) \cdot p(z) / r(s)$. When a fraction of the sample $f(s)$ is drawn from stratum s, the probability law for an observation from the pooled sample is $g(y, z) = \sum_s R(z, y, s) \cdot P(y \mid z) \cdot p(z) f(s) / r(s)$. The conditional distribution of y given z in this pooled sample is

$$\alpha_y^* + \gamma_{yv}^* = \alpha_y + \gamma_{yv} + \log\left(\sum_s R(v, y, s) \cdot f(s)/r(s)\right) g(y|z)$$

$$= \frac{P(y|z) \sum_\Theta R(z, y, s) \cdot f(s)/r(s)}{\sum_{\tau'} P(y'|z) \sum_\Theta R(z, y', s) \cdot f(s)/r(s)}$$

Note that this conditional probability depends on the marginal distribution of z only through the qualification factors.

When the sampling protocol is exogenous (i.e., $R(y, z, s)$ does not depend on y), the conditional probability $g(y \mid z)$ for the pooled sample equals the population conditional probability $P(y \mid z)$. Consequently, any statistical inference procedure designed to reveal features of the conditional probability $P(y \mid z)$ in random samples will apply to an exogenously stratified sample. In particular, if $P(y \mid z)$ is in a parametric family, then maximization of the random sample likelihood function in an exogenously stratified sample will have the same properties as in a random sample. However, in an endogenous sample in which the qualification probability $R(y, z, s)$ does depend on y, the conditional probability $g(y \mid z)$ for the pooled sample is *not* equal to $P(y \mid z)$. Consequently, statistical inference assuming that the data generation process is described by $P(y \mid z)$ is generally statistically inconsistent. Also, the distribution of covariates in an endogenous sample will differ from their population distribution, with

$$g(z) = p(z) \cdot \sum_s (f(s)/r(s)) \sum_y R(z, y, s) P(y|z)$$

and a corresponding correction factor must be applied to the sample empirical distribution of z to estimate population quantities consistently.

Manski and McFadden (1981) propose that statistical inference when $P(y \mid z)$ is parametric be based on the conditional likelihood $g(y \mid z)$, and term this the conditional maximum likelihood (CML) method. When the qualification factors $r(s)$ and sample frequencies $f(s)$ are known or can be estimated consistently from external samples, and the forms of $P(y \mid z)$ and $R(z, y, s)$ allow identification of any unknown parameters in $R(z, y, s)$, this approach is consistent. In general, the probability $g(y \mid z)$ is not in the same parametric family as $P(y \mid z)$. To illustrate, suppose a population has a binomial probit dose-response curve, $P(2 \mid z) = \Phi(\alpha + z\beta)$, and $P(1 \mid z) = 1 - \Phi(\alpha + z\beta)$. Suppose the sample consists of a randomly sampled stratum 1 with $R(z, y, 1) \equiv 1$, plus a stratum 2 drawn from the population with response $y = 2$, with $R(z, y, 2)$ equal to one if $y = 2$, and zero otherwise. This is called an enriched sample. The qualification factors are $r(1) = 1$ and $r(2) = q(2)$. If $q(2)$ is known, a consistent estimate of the slope parameter β in the dose-response curve can be obtained by the CML method with

$$g(1|z) = \frac{[1 - \Phi(\alpha + z\beta)]f(1)}{[1 - \Phi(\alpha + z\beta)f(1) + \Phi(\alpha + z\beta)[f(1) + f(2)/q(2)]}$$

By contrast, likelihood maximization using $P(y \mid z)$ is not consistent for β.

An important simplification of the CML method occurs for what in biostatistics is termed logistic regression in case-control designs. Suppose that the vector of covariates is partitioned into components $z = (v, x)$ with v discrete. (In biostatistics, v will often include variables such as age and gender whose distributions are matched between cases and controls.) Suppose that $P(y \mid v, x)$ has a multinomial logit form,

$$P(y|v,x) = \exp(\alpha_y + \gamma_{yv} + x\beta_y) / \sum_{y} \exp(\alpha_y + \gamma_{y'v} + x\beta'_y y)$$

In this model, the β_y are slope coefficients for the covariates x, and α_y and γ_{yv} are response-specific effects and interactions of response-specific and v-specific effects. Suppose that the qualification probability $R(v, x, y, s)$ does not depend on x. For identification, a normalization such as $\alpha_1 = \gamma_{1v} = \beta_1 = 0$ is imposed. The conditional probability $g(y \mid z)$ is again of multinomial logit form, with the same β_y parameters but with the remaining parameters shifted from their population values by sampling factors,

$$g(y|v,x) = \exp(\alpha^*_y + \gamma^*_{yv} + \beta_y) / \sum_{y'} \exp(\alpha'_{y'} + \gamma^*_{y'v} + \beta_{y'})$$

with

$$\alpha^*_y + \gamma^*_{yv} = \alpha_y + \gamma_{yv} + \log\left(\sum_s R(v,y,s) \cdot f(s)/r(s)\right)$$

Note that consistent estimation of this model requires the inclusion of all the alternative specific effects and interactions that are modified by sampling factors. However, if these variables are included, then the slope parameters β_y are estimated consistently without further adjustments for endogenous sampling. (If the raising factors are estimated rather than known, there is an additional contribution to the asymptotic covariance matrix (Hsieh et al., 1985). If the model had included interactions of v and x, then the coefficients on these interactions would contain sampling factors that must be removed to obtain consistent estimates of the corresponding population interactions). The simplification above was first noted by Anderson (1972).

Another solution to inference in choice-based samples is the weighted exogenous sample maximum likelihood (WESML) method proposed by Manski and Lerman (1977) in their seminal paper on this subject. This solution weights the observations, with a weight for (y, z) that is inversely proportional to $\sum_s R(z, y, s) \cdot f(s) / r(s)$. When these weights are finite and can be calculated or estimated from external data, consistent estimates can be obtained when the weighted observations are treated *as if* they were drawn from an exogenous sample. This is a pseudo-maximum likelihood method, and the associated covariance matrix will be of the sandwich form, with an outer product of the pseudo-score in the middle and the inverse of the pseudo-information matrix on the outside. For the case of pure outcome-based sampling, where the strata correspond to the possible values of y and $R(y, z, s)$ is one when $y = s$ and zero otherwise, the weights are $r(y) / f(y)$, the ratio of the population to the sample frequency of observing y.

A third approach to inference in outcome-based samples, developed by Cosslett (1981), achieves a semiparametric efficiency bound when $P(y \mid z)$ is parametric. This estimator is derived by maximum likelihood estimation that first formally concentrates out the marginal probability $p(z)$. The result is an objective function similar to $g(y \mid z)$, but with parametric sampling factors that satisfy side conditions. Hsieh et al. (1985) adapt Cosslett's analysis to improve the efficiency of the CML method in the presence of auxiliary information.

Extensions and Related Issues

Closely related to outcome-based sampling in the form described here is the problem of analyzing samples that are subject to self-selection. Several strands in the statistical and econometric literature have investigated estimators appropriate to such data: a seminal paper by Heckman (1974) on sample selection, further work on endogenous stratification by Hausman and Wise (1977), and related work on switching regression by Goldfeld and Quandt (1975).

Extensions of the basic framework for inference in outcome-based samples have been made for a variety of problems. Breslow (1996) provides methods for complex case-control sample designs. Imbens (1992) provides methods for combining outcome-based survey data with aggregate statistics. Imbens and Lancaster (1996) and McFadden (in press) have studied the problem of analysis of endogenously recruited panels.

Conclusions

Samples in observational studies often fail to qualify as random or exogenously stratified, and instead have the properties of endogenous or outcome-based samples. This may occur inadvertently due to attrition, self-selection, or stratification that is correlated with the response being studied, or may result from deliberate design decisions to facilitate

observation, as in case-control studies. This article has described the robustness issues and inference methods that are relevant for these samples.

Observational Studies: Overview

Paul R Rosenbaum, Wharton School, University of Pennsylvania, Philadelphia, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

An observational study is an empirical but nonexperimental investigation of the effects caused by a treatment. In an experiment, such as a clinical trial, the investigator assigns subjects at random to treatment groups ensuring that comparable subjects receive competing treatments. In an observational study, the investigator does not control the assignment of treatments, with the consequence that the individuals in different treatment groups may not have been comparable prior to treatment. Analytical adjustments, such as matching, are used to remove overt bias, that is, pretreatment differences that are accurately measured and recorded. In addition, there may be pretreatment differences that were not recorded, called hidden bias. An observational study is designed to permit detection of the most plausible hidden biases. In addition, the analysis of an observational study investigates the sensitivity of conclusions to hidden biases of plausible magnitudes. Strategies for making studies less sensitive to unmeasured biases are discussed.

Introduction

Definition

Cochran (1965) defined an *observational study* as a comparison of treated and control groups in which

> the objective is to elucidate cause-and-effect relationships [… in which it] is not feasible to use controlled experimentation, in the sense of being able to impose the procedures or treatments whose effects it is desired to discover, or to assign subjects at random to different procedures.

Treatments, policies, and interventions that are expected to benefit recipients can be studied in experiments that randomly allocate experimental subjects to treatment groups, so comparable subjects receive competing treatments (Boruch, 1997; Piantadosi, 2005). Observational studies are common, nonetheless, in most fields that study the effects of treatments on people, because harmful or unwanted treatments cannot be imposed on human subjects. When treatments are not randomized, subjects assigned to competing treatments may not be comparable, so differences in outcomes may or may not be effects caused by the treatments (Rubin, 1974).

Examples

Two examples of observational studies are described. Later sections refer to these examples.

Long-Term Psychological Effects of the Death of a Close Relative

Lehman et al. (1987) attempted to estimate the long-term psychological effects of the sudden death of a spouse or a child in a car crash. Starting with 80 bereaved spouses and parents, they matched 80 controls drawn from 7581 individuals who came to renew a driver's license, matching for gender, age, family income before the crash, education level, number and ages of children. Contrasting their findings with the views of Bowlby and Freud they concluded:

> Contrary to what some early writers have suggested about the duration of the major symptoms of bereavement … both spouses and parents in our study showed clear evidence of depression and lack of resolution at the time of the interview, which was five to seven years after the loss occurred.

Effects on Children of Occupational Exposures to Lead

Morton et al. (1982) asked whether children were harmed by lead brought home in the clothes and hair of parents who were exposed to lead at work. They matched children whose parents worked in a battery factory to unexposed control children of the same age and neighborhood, comparing the level of lead found in the children's blood, finding elevated levels of lead in exposed children.

In addition, they compared exposed children whose parents had varied levels of exposure to lead at the factory, finding that parents who had higher exposures on the job, in turn, had children with more lead in their blood. Finally, they compared exposed children whose parents had varied hygiene upon leaving the factory at the end of the day, finding that poor hygiene of the parent predicted higher levels of lead in the blood of the child.

Central Issues

Without random assignment of treatments, treated and control groups may not have been comparable prior to treatment, so differing outcomes may reflect either biases from these pretreatment differences or else effects actually caused by the treatment. The difficulty in distinguishing treatment effects from biases is the key consequence of the absence of randomization.

A variable measured prior to treatment is not affected by the treatment and is called a covariate. A variable measured after treatment may have been affected by the treatment and is called

an outcome. An analysis that does not carefully distinguish covariates and outcomes can introduce biases into the analysis where none existed previously.

A pretreatment difference between treated and control groups is called an *overt bias*, if it is accurately measured in the data at hand, and it called a *hidden bias*, if it is not measured. For instance, if treated subjects are observed to be somewhat older than controls, and if age is recorded, then this is an overt bias. If treated subjects consumed more illegal narcotics than controls, and if accurate records of this are not available, then this is a hidden bias. Typically, overt biases are immediately visible in the data at hand, while hidden biases are a matter of concerned speculation and investigation.

In most observational studies, an effort is made to remove overt biases using one or more analytical methods, such as matched sampling, stratification, or model-based adjustments such as covariance adjustment. Adjustments are discussed in Section Adjusting for Overt Biases. Once this is accomplished, attention turns to addressing possible hidden biases, including efforts to detect hidden biases and to study the sensitivity of conclusions to biases of plausible magnitude. Hidden biases are discussed in Sections Detecting Hidden Bias; Appraising Sensitivity to Hidden Bias; Reducing Sensitivity to Hidden Bias.

Adjusting for Overt Biases

Matched Sampling

Selecting from a Reservoir of Potential Controls

Matching is the most direct and intuitive method of adjustment, in which an effort is made to compare each treated individual to one or more comparable controls. Matched sampling is most common when a small treated group is available together with a large reservoir of potential controls (Rosenbaum, 2010: Part II; Stuart, 2010). For instance, in the study of bereavement by Lehman et al. (1987), there were 80 bereaved spouses and parents and 7581 potential controls, from whom 80 matched controls were selected.

The structure of the bereavement study is typical; computerized administrative records aid in identifying and matching treated and control subjects, but additional information is required from matched subjects for research purposes; in this case, psychiatric outcomes are required. Often it is not practical to obtain the needed research data from all controls in the reservoir and instead a sample of controls is used. Matched sampling selects controls who appear comparable to treated subjects.

Goals of Matching

Matching attempts to do three things: (1) produce matched pairs or sets that appear similar in terms of observed covariates, (2) produce treated and control groups with similar distributions of observed covariates, (3) remove that part of the bias in estimated treatment effects that is due to overt biases or imbalances in observed covariates. For instance, with pairs matched for age, goal (1) would be accomplished if each treated subject were matched to a control of the same age, whereas goal (2) would be accomplished if the entire treated group had an age distribution that closely resembled the age distribution in the matched control group, for instance, the same mean age, the same quartiles of the age distribution, and so on.

It is possible to demonstrate (Rosenbaum and Rubin, 1983) that goal (1) suffices but is not necessary for goal (2), and that goal (2) suffices for goal (3). Pairs that are individually matched for age will balance age, but it is also possible to balance age with matched pairs that are not individually matched for age, and any matching that balances the distribution of age removes the part of the bias in estimated treatment effects due to imbalances in age. This is fortunate, because it is difficult to match individually on many covariates at once, but it is not so difficult to balance many covariates at once. For instance, with 20 binary covariates, there are 2^{20} or about a million types of individuals, so even with thousands of potential controls, it will often be difficult to find a control who matches a treated subject on all 20 covariates. Nonetheless, balancing 20 covariates is often quite feasible. As a result, modern matching algorithms focus on balancing covariates, while comparability within pairs plays a secondary role. A tool in balanced matching is the propensity score.

Propensity Score

The *propensity score* is the conditional probability of receiving the treatment rather than the control given to the observed covariates (Rosenbaum and Rubin, 1983). Note carefully that the propensity score is defined in terms of the observed covariates, even if there may be hidden biases due to unobserved covariates. In the simplest randomized experiment, treatment or control is assigned by the flip of a fair coin, and the propensity score equals one-half for all subjects no matter what covariates are observed. In an observational study, subjects with certain observed characteristics may be more likely to receive either treatment or control, so the propensity score varies with these observed characteristics.

Matching on one variable, the propensity score, tends to balance all of the observed covariates. Matching on the propensity score together with a few other observed covariates – say, matching on the propensity score together with age and gender – also tends to balance all of the observed covariates. If it suffices to adjust for the observed covariates – that is, if there is no hidden bias due to unobserved covariates – then it also suffices to adjust for the propensity score alone. These results are theorems 1 through 4 of Rosenbaum and Rubin (1983).

In practice, the propensity score is unknown and must be estimated. For instance, one might estimate the propensity score using logistic regression of assigned treatment on observed covariates, perhaps with interactions and other transformations. Matching on a single variable, such as the estimated propensity score, is often practical whereas matching on many covariates is not; yet matching on the propensity score balances many covariates.

Matching Algorithms

Modern matching algorithms formulate matching as the solution to an optimization problem. Often, the optimal match minimizes the total covariate distance within disjoint matched

pairs or matched sets subject to constraints that force covariate balance (Rosenbaum, 2010: Part II; Stuart, 2010; Zubizarreta, 2012). A common covariate distance severely penalizes mismatches for the estimated propensity score and adds a robust Mahalanobis distance using key covariates (Rosenbaum, 2010: Chapter 8). Additional constraints such as 'fine balance' require perfect balance for that a nominal covariate, perhaps with thousands of levels, without constraining who is matched to whom (Rosenbaum, 2010: Chapter 10; Zubizarreta, 2012; Zubizarreta et al., 2013). In full matching, disjoint matched sets may have one treated subject and several controls or one control and several treated subjects; it is the form of an optimal stratification (Hansen, 2004; Stuart and Green, 2008; Rosenbaum, 2010: Section 8.6; Stuart, 2010: Section 3.2.2).

Several packages in the R statistical system construct optimal matched samples. The pairmatch and fullmatch functions in Hansen's (2007) optmatch package in R produce optimal treatment vs control matched pairs or sets. The nbpMatching package in R creates optimal matches without prespecified groups; see Lu et al.'s (2011) for a review of how this package may strengthen an instrumental variable or match with doses or match with longitudinal treatment assignment. Zubizarreta's (2012) mipmatch package in R implements a flexible form of optimal matching subject to balance constraints.

Model-Based Adjustments

Matched sampling compares treated subjects directly to actual controls who appear comparable in terms of observed covariates. For instance, as noted in Section Long-term Psychological Effects of the Death of a Close Relative, Lehman et al. (1987) compared bereaved individuals to matched controls who were comparable in terms of age, gender, income, education, and family structure. In contrast, model-based adjustments, such as covariance adjustment, use data on treated and control subjects without regard to their comparability, relying on a model, such as a linear regression model, to predict how subjects would have responded under treatments they did not receive.

If the model used for model-based adjustment is precisely correct, then model-based adjustments may be more efficient than matching, producing estimates with smaller standard errors. On the other hand, if the model is substantially incorrect, model-based adjustments may not only fail to remove overt biases, they may even increase them, whereas matching and stratification are fairly consistent at reducing overt biases (Rubin, 1979).

Alas, in practice, one can often detect substantial errors in a model, but rarely can have much confidence that the model is precisely correct, so there is rarely a clear choice between efficiency of model-based adjustments when the model is true and the robustness of matching and stratification when it is not. This has led to the use of combined techniques.

In simulation studies, Rubin (1979) compared matching, covariance adjustment, and combinations of these techniques, concluding that the use of covariance adjustment within matched pairs was superior to either method alone, being both robust and efficient.

Detecting Hidden Bias

Elaborate Theories

In an observational study, the investigator takes active steps to detect hidden biases – to collect data recording visible traces of unobserved pretreatment differences if they exist. In this, the investigator is aided by an 'elaborate theory,' defined by Sir Ronald Fisher in the following discussion from Cochran (1965: Section 6)

> About 20 years ago, when asked in a meeting what can be done in observational studies to clarify the step from association to causation, Sir Ronald Fisher replied: 'Make your theories elaborate.' The reply puzzled me at first, since by Occam's razor, the advice usually given is to make theories as simple as is consistent with known data. What Sir Ronald meant, as subsequent discussion showed, was that when constructing a causal hypothesis one should envisage as many different consequences of its truth as possible, and plan observational studies to discover whether each of these consequences is found to hold.

Consider the study of lead exposures by Morton et al. (1982), discussed in Section Effects on children of occupational exposures to lead. Their elaborate theory made three predictions: (1) higher lead levels in the blood of exposed children than in matched control children, (2) higher lead levels in exposed children whose parents had higher exposure on the job, and (3) higher lead levels in exposed children whose parents practiced poorer hygiene upon leaving the factory. Since each of these predictions was consistent with observed data, to attribute the observed associations to hidden bias rather than an actual effect of lead exposure, one would need to postulate biases that could produce all three associations. The use of elaborate theories and further examples are discussed in Campbell and Stanley (1963), Campbell (1988), Rosenbaum (2002: Chapters 6–9; 2010: Chapters 5, 17, and 19), Shadish et al. (2002), and Sobel (2000).

Two Control Groups

The simplest and perhaps the most common study design to detect hidden bias uses two control groups. Since none of the control group received the treatment, systematic differences between the control groups cannot be effects of the treatment and must instead be some form of hidden bias. One seeks two control groups that would differ in their outcomes if a specific unobserved bias was present. In this way, hidden biases should produce a difference between the two control groups, whereas an actual treatment effect should produce relatively similar results in the two control groups and a different result in the treated group.

This is the principle of 'control by systematic variation,' which is due in general to Bitterman (1965), and is applied to observational studies by Campbell (1969) and Rosenbaum, (2002: Chapter 8, 2010: Chapters 5 and 19). If one cannot ensure comparability of treated and control groups with respect to a particular variable, say by matching, because that variable cannot be observed, then one seeks two control groups that are known to differ markedly on that unobserved variable, that is, to systematically vary the unobserved variable. Control by

systematic variation is an instance of 'strong inference' in the sense discussed by Platt (1964). Heller et al. (2010) use a computerized construction to build a second control group by not matching for certain observed covariates that are possibly innocuous, that is, possibly without influence on the outcome.

Appraising Sensitivity to Hidden Bias

The analytical adjustments discussed in Section Adjusting for Overt Biases can often remove overt biases accurately recorded in the data at hand, but there is typically a legitimate concern that treated and control groups differed prior to treatment in ways that were not recorded. A sensitivity analysis asks how such hidden biases might alter the conclusions of the study.

The first formal method of sensitivity analysis was developed to aid in appraising the effects of cigarette smoking on human health. Responding to objections that smoking might not cause lung cancer, but rather that there might be a genetic predisposition both to smoke and to develop lung cancer, Cornfield et al. (1959: p. 40) wrote:

> … if cigarette smokers have nine times the risk of nonsmokers for developing lung cancer, and this is not because cigarette smoke is a causal agent, but only because cigarette smokers produce hormone X, then the proportion of hormone X-producers among cigarette smokers must be at least nine times greater than among nonsmokers.

This statement was an important conceptual advance. It is, of course, commonly understood that association does not imply causation – that any observed association can be explained by a hypothetical argument, perhaps an implausible hypothetical argument, postulating an unobserved variable. Although this common understanding is always correct, it contributes little to our appraisal of an observational study, because it makes no reference to what was actually observed in this empirical investigation, and no reference to scientific knowledge about the phenomenon under study. A sensitivity analysis replaces the statement – 'association does not imply causation' – by a specific statement about the magnitude of hidden bias that would need to be present to explain the associations actually observed. Strong associations in large studies can only be explained by large, perhaps implausible, biases. Aspects of the method of Cornfield et al. (1959) are discussed by Greenhouse (1982). Although important as a conceptual advance, this method of sensitivity analysis is limited in that it ignores sampling error produced by having a finite sample rather than the population as a whole, and it is applicable only to binary outcomes.

A related method addresses sampling error and may be used with outcome measures of all kinds. Observing that in a randomized experiment, subjects in the same stratum or matched set have the same probability of receiving the treatment rather than the control, the sensitivity analysis introduces a sensitivity parameter Γ, which measures the degree of departure from random assignment of treatments. Specifically, two subjects who look the same in terms of observed covariates, and so are in the same matched set or stratum, may differ in their odds of receiving the treatment by at most a factor of Γ. In a randomized experiment, $\Gamma = 1$. If $\Gamma = 2$ in an observational study, then if two people look the same in terms of observed covariates, one might be twice as likely to receive the treatment as the other because they differ in terms of a covariate not observed. For each value of Γ, it is possible to place bounds on conventional statistical inferences – e.g., for $\Gamma = 2$, perhaps, the true p-value is unknown, but must be between 0.001 and 0.021. Similar bounds are available for point and interval estimates. One then asks, How large must Γ be before the conclusions of the study are qualitatively altered? If the conclusions change for $\Gamma = 1.05$, then the study is very sensitive to hidden bias – very small departures from a randomized experiment can explain the observed association between treatment and outcome – but if the conclusions do not change for $\Gamma = 5$, then only quite dramatic hidden biases can explain the observed association. A nontechnical introduction to this method of sensitivity analysis is given in Rosenbaum (1991), and a detailed development in Rosenbaum (2002: Section 4). In R, methods of this type are available in the senmv function of the sensitivitymv package, in the adaptive.noether.brown function of the SensitivityCaseControl package, and in Luke Keele's rbounds package.

Methods of sensitivity analysis are discussed by Copas and Li (1997), Cornfield et al. (1959), Diprete and Gangl (2004), Gastwirth (1992), Greenhouse (1982), Liu et al. (2013) and Rosenbaum (2002, 2010), among others.

Reducing Sensitivity to Hidden Bias

The Goals: Smaller Unmeasured Biases; Results that Are Insensitive to Larger Biases

Given the choice, one would prefer conclusions insensitive to hidden biases, so that there is less ambiguity about the effects caused by the treatment. In part, this means selecting circumstances for the study so that plausible unmeasured biases are not extremely large. In part, this means designing the study so that it is likely to be insensitive to larger biases. For a fixed study design, as the sample size increases without bound, there is limiting sensitivity to unmeasured biases called the design sensitivity (Rosenbaum, 2004, 2010: Part III; Zubizarreta et al., 2013; Stuart and Hanna, 2013). Eventually, in large enough samples, the study will be insensitive to biases smaller than the design sensitivity and sensitive to biases larger than the design sensitivity. We prefer a study setting and design in which anticipated biases are not large, but the design sensitivity is large. A diverse collection of strategies used in observational studies may be viewed as efforts to bring about this situation.

This section first discusses the choice of circumstances for the study so anticipated biases are not extremely large. Then attention turns to instrumental variables. Finally, aspects of study design that affect design sensitivity are discussed.

Choice of Circumstances

In the earliest stages of planning an observational study, the investigator chooses the circumstances in which the study will be conducted. These choices often affect both the size of the treatment effect and the magnitude of hidden bias that is

plausible. As a result, these choices affect the sensitivity of the study to hidden bias. Some illustrations of this use of 'choice' will be briefly mentioned. See Rosenbaum (1999, 2002: Chapter 11) for detailed discussion of these cases and others with examples, and see Meyer (1995), Angrist and Krueger (1999), Vandenbroucke (2004), Dunning (2012), and Sekhon and Titiunik (2012) for related discussion.

The investigator examines a broad research hypothesis, one that makes predictions about innumerable circumstances, but examines that hypothesis in particular circumstances where dramatic effects are anticipated, free of distortions from other factors that affect these same outcomes. The investigator seeks a situation in which there is a genuine control group completely shielded from the treatment, and a treated group that received the treatment at an intense dose. One prefers a treatment that is imposed suddenly, not gradually, and haphazardly, not in direct response to characteristics of the individuals under study.

For instance, in the study in Section Long-term Psychological Effects of the Death of a Close Relative by Lehman et al. (1987), the effects of bereavement were studied following sudden deaths of close relatives from car crashes. Moreover, employing standardized criteria, they used only those car crashes for which the victim's car was not responsible, reasoning that alcohol or drug abuse or certain forms of psychopathology might increase the risk of a car crash and also be associated with unfavorable psychological outcomes in the family.

As another example, Angrist and Lavy 1999 studied the effects of class size on academic achievement in carefully chosen circumstances. In Israel, a rule dating back to Maimonides requires class rooms with no more than 40 students, so a class with 41 students is divided in two classes of about 20 students. Whereas in the United States, a class of size 40 is likely to be found in a different economic environment from a class of size 20, in Israel a comparatively haphazard event – the enrollment of an additional child – often separates these two situations.

Instrumental Variables

In some circumstances, the treatment assignment itself is subject to hidden biases that are plausibly quite large, but there is another variable, called an instrument, which has no effect on the outcome, but is associated with the treatment. The hope, sometimes realistic, is that instrument is free of hidden bias, or at least that it is affected by hidden biases that are much smaller. In an instrumental variable analysis, the magnitude of the treatment effect is modeled in terms of the treatment received, but the assignment variable is the instrument, not the treatment.

A nice example with a clear theoretical development is given by Angrist et al. (1996). They consider aspects of the health effects of military service, but of course, people who serve in the military differ in many ways from those who do not. Their instrument is the draft lottery in use in the United States between 1970 and 1973. Many people who were drafted did not serve, and many who served were not drafted, so the draft is not at all the same as the treatment under study, namely military service. However, the draft was close to random, so it is not plausible that it is affected by large hidden biases. The instrumental variable analysis models the treatment effect in terms of actual service, but uses the draft as the 'assignment variable' in a sense made precise in Angrist et al. (1996) and in the discussion published with that paper.

An instrument is said to be weak, if changes in the instrument have only slight impact on exposure to the treatment. Bound et al. (1995) show that weak instruments create problems for conventional methods of analysis, such as two-stage least squares, so 95% confidence intervals have coverage that is far below 95%. More importantly, weak instruments are invariably sensitive to small unmeasured biases (Small and Rosenbaum, 2008). Baiocchi et al. (2010) use optimal nonbipartite matching to strengthen a weak instrument, thereby reducing both of the problems with weak instruments.

Tactics to Increase Design Sensitivity

The degree to which a study design is sensitive to unmeasured biases – more precisely, the design sensitivity – is affected by many factors over which the investigator may exert some control. To understand how design sensitivity behaves is to know how to make design decisions that will affect the degree to which the study is sensitive to unmeasured biases. This rather large topic is surveyed in Rosenbaum (2010: Part III), but a few aspects can be described briefly here. If the treatment under study comes in various doses or magnitudes of treatment, and if larger doses produce larger effects, then a study that eliminates negligible and small doses will have a larger design sensitivity (Rosenbaum, 2010: Section 17.3). The same treatment effect seen with less dispersion will have a larger design sensitivity, so a smaller study in which matched pairs are more homogeneous may exhibit less sensitivity to unmeasured biases than a much larger study of heterogeneous pairs, providing the typical effect is the same in both studies (Rosenbaum, 2010: Chapter 15). Some treatments affect only a fraction of the people who receive the treatment, and in this case studies that look at typical or average treatment effects will be more sensitive to unmeasured biases than studies that emphasize the affected portion of the distribution of treatment effects (Rosenbaum, 2010: Chapter 16). In general in an observational study, to know how to decide between two choices in design is to know how those choices affect the design sensitivity.

Abstract

Obsessive-Compulsive Disorder (OCD) is a chronic, disabling disorder that is characterized by the presence of obsessions and/or compulsions. OCD groups with other related disorders such as body dysmorphic disorder, hoarding disorder, trichotillomania (hair-pulling disorder), excoriation (skin-picking) disorder, and other disorders. However, it is important to note that this group of disorders guard close proximity with anxiety disorders. The prognosis of OCD improved dramatically with the introduction of special cognitive-behavioral techniques and the use of selective serotonin reuptake inhibitors. At present, researchers attempt to integrate psychological, behavioral, neurochemical, and neuroanatomical findings in a comprehensive psychobiological model of OCD.

Obsessive-Compulsive Disorder (OCD) is a chronic, disabling disorder that is characterized by the presence of obsessions and/or compulsions. Obsessions are recurrent and persistent thoughts, urges, or images that are experienced as intrusive and unwanted, whereas compulsions are repetitive behaviors or mental acts that an individual feels driven to perform in response to an obsession or according to rules that must be applied rigidly (APA, 2013). They cause marked distress and considerably interfere with daily functioning. For decades, OCD has been considered to be treatment-refractory. The first major advance was the observation that clomipramine, which differs from other tricyclic antidepressants by its potent inhibition of serotonin reuptake, proved to exert specific antiobsessional effects. The prognosis of OCD improved dramatically with the introduction of special cognitive-behavioral techniques (CBT) and the use of selective serotonin reuptake inhibitors (SSRIs). These specific therapeutic effects and other indices of altered serotonergic function were the background for a serotonergic hypothesis of OCD. The results of new neuroimaging techniques have produced evidence for basal ganglia involvement in the pathogenesis of OCD. In summary, it has been postulated that a disturbed striatal filter function causes a disinhibition of cerebral activities generated in orbitofrontal and cingulate structures. Positron emission tomography (PET) studies have also demonstrated that neurobiological changes associated with OCD are modulated by both pharmacological and psychological treatments. At present, researchers attempt to integrate psychological, behavioral, neurochemical, and neuroanatomical findings in a comprehensive psychobiological model of OCD.

The Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5; APA, 2013) proposes the OCD grouping with other related disorders such as body dysmorphic disorder, hoarding disorder, trichotillomania (hair-pulling disorder), excoriation (skin-picking) disorder, substance/medication-induced obsessive–compulsive (OC) and related disorder, OCD and related due to another medical condition, and other OCD and related specified and unspecified OCD. The inclusion of a specific chapter for OC and related disorders in DSM-5 reflects a progressive increase in scientific evidence that relate these disorders to each other with a series of diagnostic validators, and also the clinical utility of grouping these disorders (APA, 2013). However, it is important to note that this group of disorders guard close proximity with anxiety disorders.

Clinical Aspects

Clinical Symptomatology and Course

OCD is a chronic, disabling disorder that is characterized by recurrent obsessions and uncontrolled compulsions. Obsessions are defined as persistent ideas, thoughts, impulses, or images that are experienced as intrusive and inappropriate. Usually patients attempt to ignore or suppress the obsessions, which typically deal with contamination, doubts, or aggressive imaginations. Compulsions are repetitive behaviors (e.g., handwashing, checking locked doors) or mental acts (e.g., counting, repeating words) that the person feels driven to perform in response to an obsession or according to rigid rules. Characteristically, compulsions counteract the anxiety associated with an obsession. Diagnosis by DSM-5 also requires that the obsessions or compulsions are time-consuming (e.g., take more than 1 h per day) or cause clinically significant distress or impairment on social, occupational, or other important areas of functioning (APA, 2013).

Twenty-five percent of the cases of OCD start by 14 years. In the U.S., the mean age at onset is 19.5 years. Onset after 35 years is unusual but does occur. Males have an earlier onset than females (APA, 2013). The disorder tends to exhibit a waxing and waning course over the life span, with periods of relative good functioning and limited symptoms punctuated by periods of symptomatic exacerbation. A small minority of subjects exhibits either complete remission of their disorder or a progressive, deteriorating course. There is a high comorbidity with major depression, panic disorder, phobias, and eating disorders. Approximately half of all patients with Tourette's disorder meet criteria for OCD, although less than 11% of patients with OCD meet criteria for Tourette's disorder.

Differential Diagnosis

OC symptomatology is also found in various other psychiatric disorders. It can be difficult to differentiate OCD from major depression, which is sometimes associated with obsessive thoughts. In contrast to OCD, obsessional thinking in depression usually subsides in parallel to the remission of depression. Psychotic symptoms can also provoke obsessive thoughts and compulsive behaviors, but are accompanied by other characteristics of schizophrenia. Principally, OCD patients differ from schizophrenic patients by their knowledge that obsessions and compulsions are inappropriate, absurd, or irrational ('ego-dystonic'). However, when the condition is very severe the patient might experience his obsessions or compulsions as more ego-syntonic and is transiently not sure about the real risk of danger or the real necessity to perform a certain ritual in order to prevent a negative event. There is a subgroup of OCD patients who are frequently misdiagnosed as schizophrenic due to these 'psychosis-like symptoms.' OCD also displays some similarity to OC personality disorder, which is associated with an obsessive concern for details, perfectionism, and rigidity. However, a genuine syndrome of obsessions and compulsions is not present in OC personality disorder. Patients with OCD experience distress connected with their symptoms. By contrast, the traits of patients with OC personality disorder very often disturb others more than themselves. Finally, OCD is sometimes misdiagnosed in patients suffering from phobias (e.g., phobic avoidance of any assumed risks to be infected by the AIDS virus). However, phobic patients never develop the kind of rituals which are characteristic of OCD. Other disorders that should also be included in the differential diagnosis of OCD are hypochondria, eating disorders, generalized anxiety disorder, panic and agoraphobia disorder, and post-traumatic stress disorder (*see* Differential Diagnosis in Psychiatry).

Epidemiology

The prevalence of OCD in the various countries ranges from 1.1% to 1.8% (APA, 2013). Women are slightly more affected than men, but men are more affected than women during childhood (APA, 2013; *see* Mental Disorders, Epidemiology of).

Pathogenesis

There is strong evidence that neurobiological as well as psychological factors play an important role in the pathogenesis of OCD. Interestingly, OCD occurs across the world and there is a substantial similarity across cultures in the gender distribution, age at onset, and comorbidity of OCD (APA, 2013). Phenomenological similarities between focal dystonias and OCD are related to the persistent, perseverative, repetitive, and involuntary nature of the symptoms. The occurrence of OC symptoms as part of the postencephalitis Parkinsonian syndrome (Schilder, 1938) stimulated the search for a biological link between basal ganglia dysfunction and OC symptomatology. Compulsive behavior and obsessional thinking have been observed after basal ganglia lesions (Laplane et al., 1989; Swedo et al., 1989) and in patients with Gilles de la Tourette's syndrome (Pauls et al., 1986). Accordingly, symptomatic dystonias can be associated with structural brain lesions (Kostic et al., 1996). Patients suffering from spasmodic torticollis (Bihari et al., 1992) or from blepharospasm, conditions which are also related to basal ganglia dysfunction, showed significantly more OC symptoms than normal controls or patients with hemifacial spasms, a condition with similar symptomatology, but caused by an irritation of the facial nerve (Broocks et al., 1998b).

Neuroanatomical Hypothesis of OCD

Since around 1990 PET and other brain imaging studies have produced further evidence for basal ganglia involvement in the pathogenesis of OCD. Functional neuroimaging studies have shown an increase in metabolic activity in the orbitofrontal cortex, anterior cingulate gyrus, and caudate nucleus (Rauch, 2003). After receiving pharmacological and psychotherapy treatment, there was a reduction in the activity at these sites (Rauch, 2003). In addition, all surgical procedures for treatment of OCD refractory patients focus in the surgical disruption of these neural circuits (Lopes et al., 2009).

The pathological increase of metabolic activity in the orbitofrontal cortex (OFC) demonstrated in PET studies that most OCD patients experience the neurobiological expression of the sensations of anxiety and worry. The caudate nucleus and other striatal structures are stimulated by the OFC. Leading researchers in this field have postulated that in OCD a positive feedback mechanism between the OFC and the striatum is activated, which also involves thalamic structures. Physiologically, inhibitory pathways from the caudate nuclei to the thalamus (via the *globus pallidus*) have the task of keeping this neurosensory circuit in balance. One explanation of the proposed disbalance in OCD could be that an increased inhibition of the *globus pallidus* results in a disinhibition of the thalamus creating a self-sustaining circuit (**Figure 1**).

Neuropsychological testing has revealed that patients with OCD are impaired on measures of spatial working memory, spatial recognition, and motor initiation and execution (Purcell et al., 1998; Schmidtke et al., 1998). In contrast, performance of these tasks by patients with panic disorder or depression did not differ from that of controls.

Figure 1 The proposed self-sustaining circuit in OCD.

Neurochemical Hypothesis of OCD

The most compelling findings suggesting a role of serotonergic pathways in the symptomatology of OCD come from well-replicated treatment studies. Most OCD patients improve during treatment with serotonin (5-HT) reuptake inhibitors including clomipramine, fluoxetine, fluvoxamine, paroxetine, and sertraline, but not with non-5-HT selective antidepressants (Murphy et al., 1996; Pigott and Seay, 1999). This observation was replicated in a multicenter trial enrolling 166 patients with concurrent OCD and major depression, in which the SSRI sertraline was more effective in reducing depressive and OC symptoms than the primarily norepinephrine reuptake inhibitor desipramine (Hoehn et al., 2000). Using a placebo-controlled design, discontinuation of clomipramine was followed by an increase of OCD symptoms (Pato et al., 1991). Interestingly, coadministration of the 5-HT2 receptor antagonist metergoline to OCD patients being treated with clomipramine was associated with higher OC symptoms in comparison to placebo coadministration (Benkelfat et al., 1989). An exacerbation of OC symptoms after administration of the nonselective serotonergic agonist, *m*-chlorophenylpiperazine (*m*-CPP) was observed in several, but not all studies (Broocks et al., 1998a; Charney et al., 1988; Hollander et al., 1992; Zohar et al., 1988).

When oral *m*-CPP was readministered during chronic treatment with clomipramine (Zohar et al., 1988) or fluoxetine (Hollander et al., 1992; Pigott et al., 1990), OCD patients did not show an exacerbation of OC symptoms although plasma prolactin and cortisol responses to *m*-CPP were not attenuated. This suggests that chronic clomipramine or fluoxetine treatment in OCD patients may be associated with the development of an adaptive subsensitivity in one or more serotonergic subsystems (Murphy et al., 1996).

Genetic Findings

There is a 3- to 12-fold increased risk in first-degree relatives of patients with OCD (Pauls, 2010). There are some genes that have been linked to OCD as SLC64A and SAPAP3 (Shavitt et al., 2012). The first gene is responsible for producing serotonin transporter. The second, when not functioning properly, leads to OC symptoms in animals and also seems to be related to trichotillomania (Zücher et al., 2010).

Immunological Findings

Recently, new evidence has emerged for possible immunological factors in the pathogenesis of OCD (Teixeira et al., 2014). It has long been known that about 10–30% of patients with rheumatic fever, caused by a streptococcal infection (Skoog and Skoog, 1999), develop Sydenham's chorea. It is believed that OCD happens for a cross-reactivity of antibodies produced against streptococci within the structures of the basal ganglia of the brain that are involved in the pathophysiology of OCD (Skoog and Skoog, 1999).

Treatment

For decades, OCD has been considered as a fascinating but treatment-refractory mental condition. Conventional pharmacological approaches as well as psychodynamic therapy did not lead to satisfactory improvements of OC symptomatology. The first major advances in the treatment of OCD came from two directions. Clomipramine, which differs from other tricyclic antidepressants by its potent inhibition of serotonin reuptake, proved to exert specific antiobsessional effects. At the same time, the introduction of special CBTs began to continuously improve the prognosis of OCD. In the following years, many studies have shown that behavior therapy, especially exposure with response prevention, and SSRIs significantly reduce OC symptoms.

Psychological Treatment

Exposure/response prevention (Williams et al., 2014) has been compared to various control treatments including relaxation, anxiety management training, and pill placebo (Kozak et al., 1999), leading to solid evidence for the efficacy of this procedure. Summarizing all controlled trials, average responder rates were 83% immediately after treatment and 76% after an average follow-up interval of 29 months.

Current exposure/response prevention programs usually combine *in vivo* exercises to feared stimuli with imaginative exposure. Repeated prolonged exposure leads to a psychophysiological habituation process, which also affects irrational beliefs held by the patient. It is crucial that the duration of the exposure exercise continues at least until the patient experiences a decrease of the induced distress. During this time therapists have to be alert to detect and restrain covert neutralizing thoughts (Salkovskis, 1999). If possible, a friend or a family member should be taught to support the patient between sessions in order to achieve adequate exposure. Irrespective of the emotional arousal, the patient has the task to describe precisely the experienced emotions and the accompanying cognitions. This description is the basis of the cognitive restructuring which most therapists view as an essential component of successful exposure.

Cognitive approaches have been proposed for the treatment of OCD, especially obsessional ruminations (Salkovskis, 1999). According to the cognitive hypothesis, obsessional problems occur when intrusive cognitions are interpreted as an indication that the person may be responsible for a certain harmful event, which has happened in the past or will happen in the future. Cognitive therapy is thought to work by altering both strongly held beliefs associated with OCD symptoms and interpretations of intrusive mental experiences (**Figure 2**). It is also important to help patients to identify and to modify underlying general assumptions, which might represent the roots of the more overt dysfunctional thoughts. As in other anxiety disorders, the general style of therapy is that of guided discovery. Further details of the cognitive treatment of obsessions including the use of loop tapes are described in Salkovskis (1999).

Schwartz has proposed a cognitive-biobehavioral self-treatment for OCD (Schwartz, 1996). It integrates the results of neuroimaging research into the cognitive approach based on the literature on the behavioral neurobiology of the basal ganglia. In a four-step process, the OCD patient learns to identify his or her obsessions and compulsions, to label them

Figure 2 Cognitive therapies.

as such ('It is not me, it is my OCD'), and to attribute them to abnormal activity of the frontostriatal system. While 'working around OCD symptoms,' patients learn new adaptive responses to intrusive OCD thoughts and urges. They are tutored to become increasingly aware of avoidance behaviors and to use treatment techniques to perform previously avoided behaviors (Schwartz, 1996).

In addition to exposure, response prevention and cognitive techniques, the multimodal treatment of OCD also focuses on social deficits, reduced tolerance for intensive emotions, and reduced emotional awareness. In addition, it deals with deficits in problem-solving and self-initiated alternative behaviors as well as interpersonal problems. In severe cases, complex combinations of multimodal interventions are often needed, including marital or family interventions as well as individual or group treatments. Multimodal CBT has been shown to be effective with very low dropout rates in severely ill inpatients (Hohagen et al., 1998) and outpatients (Hand, 1998). Furthermore, its long-term efficacy has been demonstrated in follow-up studies in unselected patients (Hand, 1998). Whether multimodal behavioral therapy is superior to exposure therapy alone and whether it is appropriate to treat refusers, dropouts, and nonresponders to conventional exposure therapy with response prevention, are still open questions (*see* Behavior Therapy: Psychiatric Aspects).

Drug Treatment

In comparison to clomipramine, SSRIs have the advantage of a very low toxicity and a more favorable side effect profile. Consequently, these agents have been the focus of several large-scale, placebo-controlled studies of OCD. Interestingly, very low placebo response rates were observed in most studies. Based on meta-analyses of effect sizes in placebo-controlled trials clomipramine was considered more effective than the SSRIs. However, direct comparisons demonstrated similar efficacy between clomipramine and different SSRIs (Pigott and Seay, 1999). Pharmacological treatment of OCD usually involves relatively high daily dosages (clomipramine up to 250 mg; fluvoxamine up to 300 mg; fluoxetine, paroxetine, and citalopram up to 80 mg; and sertraline up to 200 mg a day), but some investigators believe that longer duration of treatment rather than higher dosage is essential for response. Ten weeks of treatment trial is currently the minimum recommendation, but it is not unusual to have treatment continue for several months before peak efficacy is reached. The algorithm in **Figure 3** can be recommended for the pharmacological treatment of OCD patients.

Combined Pharmacological and Cognitive-Behavioral Treatment

There seems to be superiority of combined treatment (pharmacological and psychotherapeutic) when compared to each treatment alone (Foa et al., 2005; Pediatric OCD Treatment Study, 2004; *see* Psychotherapy and Pharmacotherapy).

Prognosis

The presence of schizotypal, borderline, and avoidant personality disorders predicts a less favorable prognosis, whereas duration of illness, sex, age, and type of symptoms had no clear predictive value. In cognitive-behavioral therapy the best predictor of good outcome at the end of treatment and of follow-up was early compliance in doing exposure homework (De Araujo et al., 1996).

Figure 3 Further procedures in treatment of refractory cases.

Summary and Future Tasks

Despite all progress in treatment, a considerable percentage of patients experience only a partial unsatisfactory response (Dold et al., 2013). At least 25% of OCD patients do not comply with exposure therapy/response prevention (Schwartz, 1998). In addition to dropouts, 20–30% do not respond sufficiently. Since OCD is a chronic disorder, reoccurrence of the OCD symptomatology is likely when patients do not adhere to the newly adopted cognitive-behavioral habits due to motivational problems, acute life stress, or depression. With SSRI treatment alone, 40–60% of patients have not shown significant progress and have to be classified as nonresponders.

Resistant and refractory cases may benefit from an association of an SSRI and an atypical antipsychotic (Bloch et al., 2006), such as risperidone (up to 6 mg), quetiapine (up to 300 mg), or olanzapine (up to 20 mg). In addition, the association between Clomipramine and an SSRI is a good option for these cases (Shavitt et al., 2012). In severe and disabling cases with proven refractoriness, multiple drug interventions and CBT, surgical treatment should be considered (Lopes et al., 2004). The goals of surgical treatment of OCD are some points of the cortico–striatal–thalamic–cortical circuit (Lopes et al., 2004).

Obsessive-Compulsive Disorder across the Life Span

Norbert Kathmann, Humboldt-Universität zu Berlin, Berlin, Germany

Abstract

Obsessive-compulsive disorder (OCD) is a disabling disorder with heterogeneous symptoms. Diagnostic and Statistical Manual of Mental Disorders (Fifth edition) categorizes OCD apart from anxiety disorders, together with obsessive-compulsive spectrum disorders. Onset is frequent in childhood and adolescence but can also occur in late life. Several risk factors have been identified, with major genetic fractions. Traumatic or stressful events may play a role. Research identified alterations in brain structure and function, learning processes, action monitoring, feedback processing, and cognitive beliefs to contribute to OCD onset and development. Cognitive-behavioral psychotherapy and pharmacotherapy with serotonin reuptake inhibitors are the first-line treatments in both young and adult patients. More longitudinal research to explore the mechanisms of symptom development and maintenance as well as improved interventions together with efforts to disseminate empirically supported therapies is needed.

Phenomenology and Diagnosis

Symptoms

Obsessive-compulsive disorder (OCD) is a complex disorder that is primarily characterized by the interplay of obsessions and compulsions. Obsessions are unwanted intrusive ideas that suddenly enter consciousness and elicit distress, anxiety-like affect, or disgust. Typical obsessions are thoughts about contamination with germs, excrements, or cleansing agents, which occur in combination with the concern that these materials might infect, poison, and ultimately kill other individuals. Other contents circulate around attacking other people with a knife, hurting someone's baby, or behaving sexually inappropriate. There are many more topics that can turn into obsessive thoughts such as the lack of symmetry and order of objects, the possibility of deficient carefulness while closing a door or turning off a stove, or the possibility of performing or thinking blasphemously or immorally. Importantly, most of these ideas are contrary to the person's values and goals and impose on that person against his/her will. Compulsions are understood as responses to those obsessions that are initiated by the patient in an effort to overcome induced negative feelings, to neutralize aversive thoughts, and, ultimately, to prevent harm. Although patients usually acknowledge the irrationality of this logic, failing to perform the compulsion increases distress and leads to feelings of guilt. Examples for frequent compulsions are excessive hand washing; controlling switches and faucets for several minutes or even hours, thereby using a rigid ritual sometimes; thinking good thoughts to prevent bad events; repeating routine activities until one feels just right; ordering objects in a certain manner; counting until a specific number; or asking the same question until one feels certain. Patients feel more impaired by the obsessions whereas overt compulsions manifest as the leading symptom of OCD observable by other people. Only a minority of patients shows either obsessions or compulsions. In those cases, it is unclear whether obsessions cannot be reported or compulsions are too subtle to recognize them.

To achieve a more systematic description, attempts have been made to integrate the heterogeneous symptoms of OCD into subtypes and dimensions. The method most widely used to generate a dimensional system is factor analysis of identified symptoms. The Yale-Brown Obsessive Compulsive Scale Symptom Checklist (Y-BOCS-SC) measures more than 60 symptoms as present or not, either currently or throughout the whole lifetime. Thirteen symptom categories are determined by collapsing single items from the list on a rational basis. These categories were factor-analyzed in several studies converging in four-factor solutions. The factors were termed (1) 'taboos and forbidden thoughts' (aggressive, religious, sexual, and somatic obsessions, and checking behavior), (2) 'symmetry' (symmetry obsessions and repeating, ordering, and counting compulsions), (3) 'cleaning' (contamination obsessions and cleaning compulsions), and (4) 'hoarding' (hoarding obsessions and compulsions). An item-level factor analysis in a large sample showed the best fit for a five-factor solution consisting of (1) taboo, (2) contamination/cleaning, (3) doubts, (4) superstitions/rituals, and (5) symmetry/hoarding (Katerberg et al., 2010). Due to remaining inconsistencies, no consensus about the correct number and characterization of the symptom factors has been achieved so far. A limitation of the factor-analytic studies is that all of them are based on the Y-BOCS-SC, which was not constructed as a tool for measurement of the dimensional structure of OCD. New diagnostic instruments have been developed but require further validation before they can be used broadly. Nevertheless, dimensional diagnostics in OCD hold promise for future research because it allows for parsimonious but comprehensive description of cases, for covering heterogeneity of psychopathology, and, potentially, for refined etiological concepts.

Beyond the dimensional approach, several categorical subtypes for OCD have been suggested. *Early onset* (EO) in OCD is referred to the beginnings of the disease in childhood or adolescence. More than 50% of adults diagnosed with OCD are estimated to have EO. Latent class analysis has validated two onset groups (Taylor, 2011a). Patients with EO had a mean age of 11 years when OCD or OC symptoms were diagnosed the first time. They are more likely to be male, and report a higher global severity of symptoms in adulthood. Repeating compulsions, religious obsessions, symmetry obsessions,

checking compulsions, sexual obsessions, hoarding compulsions, and aggressive obsessions are more prevalent in adult OCD patients with EO compared to patients with late onset. Patients with EO are also exposed to a more than twofold risk of having comorbid tics. First-degree relatives of OCD patients with EO show a higher prevalence of OCD or OC symptoms than relatives of late-onset patients. These differences support the validity of the age of onset distinction. A second criterion used to categorize OCD patients in subgroups is *comorbidity with tics*. Tic-related OCD affects around one-fourth of the EO cases. Those cases are predominantly male and show more symmetry and ordering symptoms as well as taboo obsessions than other cases. Further, they report enhanced incidence of specific symptoms, like sensory phenomena, feelings of incompleteness, and higher rates of comorbidity with attention deficit hyperactivity disorder (ADHD), including disruptive behaviors. Recurrence risk for OCD is higher in first-degree relatives of tic-related OCD patients than in pure OCD cases. Response to cognitive-behavioral interventions, however, is not different for the tic-related subgroup. Although there is some overlap of the two subtyping schemes (EO and tic-related), a substantial proportion of EO patients has no tic symptoms. Therefore, and on the basis of the evidence reported above, both onset and tic comorbidity may be of value for refined etiological research and treatment.

Diagnosis

In the *Diagnostic and Statistical Manual of Mental Disorders*, fourth edition (DSM-IV) as well as in the International Classification of Diseases, tenth revision (ICD-10), the presence of either obsessions or compulsions or both are core criteria for a diagnosis. ICD-10 requires symptoms to be present over a period of at least 2 weeks whereas DSM-IV defines that symptoms must be time consuming (e.g., taking more than 1 h per day). Also, according to DSM-IV and ICD-10, the person must recognize at some point that obsessions and/or compulsions are excessive or unreasonable. In 2013, the DSM-5 was introduced, including a new chapter on OCD and related disorders. This is a significant change because OCD is no longer classified as an anxiety disorder. Besides body dysmorphic disorder, hair pulling disorder, and skin picking disorder, hoarding disorder is now a diagnosis within the 'related disorders' spectrum (formerly a symptom category or a dimension of OCD). The DSM-IV specifier 'with poor insight' was changed in the DSM-5, and is now allowing for several degrees on a spectrum of insight: good/poor/absent or delusional OCD beliefs. Consequently, patients with delusional OCD symptoms can be diagnosed as OCD and do not warrant a diagnosis of psychosis or schizophrenia. Finally, a new specifier has been introduced for tic-related OCD.

Life Span Aspects

It is important to note that repetitive and ritualistic activities are frequent among children during some phases of development. Bedtime rituals, but also activities that are hardly to distinguish from compulsive symptoms like arranging objects, may occur in early childhood peaking around 2–3 years of age. Most of these behaviors disappear before school age, but little is known on the mechanisms underlying these behaviors and on possible links to OCD. In general, the phenomenology and the range of symptoms of OCD in childhood do not differ from those of adult patients. However, some specifics have been reported in small epidemiological samples. Content of harm and aggression obsessions often involved family members, and symmetry/ordering symptoms were more frequent in children, whereas contamination/cleaning symptoms appear to be less prevalent in children. Generally, insight with respect to the irrationality of the obsessions is low in young children. Therefore, the DSM-IV has omitted insight from the criteria list for an OCD diagnosis in children. As mentioned above, comorbidity with tics and ADHD is enhanced, and more boys than girls are diagnosed with OCD in childhood.

A critical phase for female individuals prone to develop OCD is pregnancy and postpartum. Based on a meta-analysis, prevalence in pregnant women is 2%, which is twice the prevalence of women in the general population. Postpartum women are suffering from OCD even more frequently than pregnant women (Russell et al., 2013). The clinical manifestation in these cases is dominated by obsessive thoughts with aggressive contents (e.g., to hurt or kill the baby) and/or contamination fears (e.g., that dirt or germs might be transmitted and may harm the baby). Excessive avoidance, compulsive cleaning, and excessively checking on the baby are observable compulsions, aiming to ensure life and health of the baby. In the case of clinically significant symptoms, OCD can interfere with the provision of adequate care and the development of bonding. However, the majority of new parents are experiencing some transient concerns of harming their newborn, and such fears are also part of postpartum depression. Thus, diagnosing OCD in the context of pregnancy or postpartum period requires careful assessment of the degree of functional impairment and distress.

OCD symptoms appear to decline in older adults, and patients of older age are less frequently seen in psychiatric and psychotherapeutic care. However, a recent epidemiological study in population aged 70 and above showed that the condition also represents a significant burden in older age (Klenfeldt et al., 2014). This may be partly due to a chronic course of OCD with onset earlier in lifetime but also to incidence in older adulthood. Cases with an onset beyond age 60 were also found. The doubting type of obsessions is frequently present in those patients, and compulsions typically involve checking but not cleaning. Generally, there is a need for more research on OCD in older age because data on this topic is scarce to date.

Epidemiology

OCD has been presumed to be a rare disorder until epidemiological field studies revealed a different picture. According to a recent study conducted in the USA, OCD has an estimated lifetime prevalence of 2.3% and a 12-month prevalence of 1.2% (Ruscio et al., 2010). Subthreshold OC symptoms were found in nearly 30% of the community. The majority of OCD cases met the lifetime criteria for one or multiple comorbid disorders. Anxiety disorders and mood disorders are the most prevalent of these comorbid conditions. Onset of mood

disorders precede or follow the onset of OCD with almost equal probability, whereas comorbid anxiety disorders like specific and social phobia mostly emerge before OCD onset. Other studies around the world using larger community samples revealed DSM-IV-based lifetime prevalence estimations between 0.5 and 3.8%. It is unclear whether regional and cultural differences in true prevalence or methodological aspects like definition of diagnostic threshold or the diagnostic instrument administered account for this variance.

Comorbid personality disorders (PD) are also found at high rates among OCD patients. A meta-analysis showed that OCD patients have the highest comorbidity with any PD (52%) among all anxiety disorders (Friborg et al., 2013). OCPD (20%) followed by avoidant PD are the most frequent comorbid PDs.

Although gender differences in prevalence is generally lower in OCD than in most anxiety disorders and affective disorders, there is a preponderance of female patients across studies. However, age substantially moderates gender differences. Patients with very early onset (<10 years) are predominantly male, females have more incidence in adolescence, and older age patients are mostly female.

Epidemiological studies specifically addressing childhood and adolescence populations report that OCD is rare (<0.1%) below age 13, but prevalence increases exponentially in adolescence (>0.5). Prevalence estimations for adolescents aged 14–18 do not substantially differ from those in adult populations in most studies. A recent population-based study found an even higher point prevalence of 3.3%. After age 30, prevalence appears to decrease monotonically. However, according to recent evidence, there may be a higher than expected prevalence in populations aged 70 and above.

Disability and Quality of Life

According to the World Health Organization (WHO), OCD ranges among the 10 most disabling diseases, being the fifth most disabling disease among women aged 15–44. Although many patients are successful in deceiving their fellow human beings about the real nature of their problems for a long time, about two-thirds of patients have severe disabilities and role impairments, mainly in the domains of work/school, relationships, and social functioning (Ruscio et al., 2010). Disability scales measure the degree to which OCD symptoms disrupt functions like managing work, school and household, and establishing partnership and social life. The degree of impairment depends not only on symptom severity but also on the number of comorbid conditions. Quality of life (QoL) is defined by the WHO as the subjective perception of one's position in life in the context of the personal goals and the value systems, the individual is living with. In addition, it represents satisfaction with health, and with occupational, social, and other activities. Patients suffering from OCD have seriously impaired QoL as reported in several studies. The deficits were more pronounced than those in panic disorder, social phobia, and kidney transplant patients, and at a similar level as in schizophrenia and depressive disorders (Macy et al., 2013). Improvements in role functioning and QoL are increasingly recognized as the ultimate goals for interventions in addition to symptom reduction. When measured as an outcome variable, impairments have been found to be reduced both after cognitive-behavioral psychotherapy (CBT) and pharmacotherapy, though remaining above the level in the general population. Less research has been conducted on QoL in pediatric and in elderly OCD patients. Notably, there seem to be serious impairments due to OCD in these age groups as well.

Risk Factors, Etiological Models, and Pathogenetic Mechanisms

Stressful Life Events and Traumatization

Several psychological factors that qualify to be etiologically relevant have been confirmed by empirical studies. Stressful life events are a general risk for the incidence of mental disorders and are also associated with OCD. They are assumed to trigger disease onset or to interact with biological factors and, thereby, contribute to the development of the disorder. Children with OCD were reported to have experienced more stressful events within 1 year before diagnosis than healthy children. Also, risk factors like pregnancy and the postpartum period typically implicate stressful events. In addition to everyday stress, traumatic events have been implicated in the etiology of OCD. Retrospectively, lifetime traumatic events were found in more than 50% of adult OCD patients. Present symptom severity, in particular checking and ordering, correlates with traumatic events in the past. Sexual as well as physical abuse before the age of 11, and a number of residence changes are prospectively associated with OCD. Furthermore, loss of a parent predicted checking symptoms (Grisham et al., 2011). However, some studies did not find differences in severe traumatization between OCD patients and controls. Overall, traumatization and comorbid trauma-related symptoms might be more relevant in severe and treatment-resistant cases. Parental rearing style is another candidate risk factor for OCD. In some studies, less paternal or parental warmth and more paternal or parental rejection and control were reported. However, diagnostic specificity is unlikely, and the retrospective nature of the studies limits their validity. A recent meta-analysis on twin studies assessing OC symptoms revealed that only a small proportion of variance (6%) is accounted for by shared environmental factors while more than 50% are related to nonshared environment (Taylor, 2011b). The latter proportion increases with age.

Genetics

Genetic factors contribute to mental disorders, and this applies for OCD as well. In fact, meta-analytic estimates of the variance explained by additive genetic factors amount to 38% (Taylor, 2011b). Family studies support the putative role of genetic effects for transmission of OCD. The risk to develop OCD for an individual with a family member already presenting with OCD is about four times higher than in the general population. Relatives of individuals with early age of onset have an even higher risk. Despite such consistent results in population genetic studies, there is little clarity about specific gene variants contributing to this risk so far. Many associations of OCD and functional candidate genes have been detected but successful

replications are rare. In a meta-analysis including 20 polymorphisms analyzed in at least five studies, variants of genes related to the serotonergic system (5-HTTLPR and HTR2A) and to catecholamine modulation (COMT and MAOA), with the latter in males only, were confirmed to be associated with OCD (Taylor, 2013). Less consistent were associations with dopamine-related polymorphisms (DAT1 and DRD3) and with the glutamate system (SLC1A1). Genome-wide association studies as well as further meta-analyses were not able to clarify the exact role of specific genes for the etiology of OCD, but the glutamate transporter gene appears to be involved. Even larger samples will be necessary to identify critical gene variants. Based on the present results, it can be concluded that many genes with small effects are likely to contribute to the genetic risk for OCD.

While a pure genetic explanation of OCD is incompatible with current findings, the fact that about 40% of the phenotypic variance in OC symptoms is accounted for by genetic variance clearly calls for incorporation of genetic factors in a comprehensive model of OCD. There is growing insight that future research must have a focus on gene-by-environment interactions, i.e., the effects of negative life events might come into play only or to a stronger degree in the presence of certain gene variants. One of the first studies of this type showed that emotional abuse and neglect during childhood increased the risk of having OCD, and this effect was enhanced in individuals with the BDNF Met-allele (Hemmings et al., 2013).

Immunological Factors

Infection with group A beta-hemolytic streptococcal bacteria has been suggested as a risk factor for OCD and tic disorder, since there are a number of childhood OCD cases with sudden symptom exacerbation after such an infection. The inflammation produces an autoimmune response involving antibasal ganglia antibodies, which are implicated in Sydenham chorea, a transient movement disorder frequently associated with OC symptoms, but OCD symptoms may also occur without movement disorder. The term PANDAS (pediatric autoimmune neuropsychiatric disorders associated with streptococcal infection) was introduced to indicate such cases. However, there is still some controversy about whether the presence of the antibodies is pathogenetically relevant for OCD or rather an epiphenomenon (da Rocha et al., 2008). Possibly, PANDAS concerns a relatively small subgroup of OCD patients with a different etiology and phenomenology. Antibiotic and immunomodulatory therapies have been proposed for those patients but require further evaluation.

Other Biological Risk Factors

Preterm birth and maternal health problems during pregnancy have been occasionally reported to be more prevalent among OCD cases. Maternal age at birth was associated with increased risk to develop OCD in a large-scale study, but it is known that this association also holds for other mental disorders. Based on a longitudinal study, perinatal complications were linked to obsessive shameful thoughts but not to OCD incidence in general (Grisham et al., 2011).

Pathogenetic and Etiological Models of OCD

Psychological Models

The first pure psychological model to account for OCD was developed by Sigmund Freud and later refined by psychodynamic theorists. Briefly, according to psychoanalytic theory, obsessional thoughts and compulsive acts are the results of a conflict between sexual and aggressive impulses, and the repression of those impulses. Due to fixation in the so-called anal phase of psychosexual development, the ego uses specific defense mechanisms to reconcile the forbidden impulses, thereby forming the symptoms as a compromise. However, only little empirical research was devoted to support this model. Therefore, it plays a minor role in modern concepts of understanding and treating OCD.

Behavioral models have received much more empirical attention. The most influential one is the two-factor model of fear development and maintenance by Mowrer (1960). It assumes that classical conditioning leads to the acquisition of fearful thoughts, and operant conditioning involving fear-neutralizing rituals makes the individual resistant to extinction. The latter component represents the target of the dominating intervention technique for OCD, namely exposure and response prevention (ERP). However, although a fraction of OCD patients actually report traumatic events before the onset of symptoms, empirical evidence for associative learning as a major mechanism for pathogenesis is limited. Extinction actually appears to be compromised both by excessive use of avoidant behaviors and putatively by a neurobiologically based impairment in extinction recall.

Cognitive models assume that symptoms may arise from dysfunctional cognitive contents and beliefs. They stimulated plenty of empirical studies, and are broadly accepted by practitioners, in particular by those applying CBT. In the case of OCD, inflated personal responsibility beliefs and the idea of thought–action fusion are presumed to induce negative appraisals of intrusive thoughts, and consequently negative affects like shame, guilt, and anxiety will arise. Compulsive rituals are adopted as a means to prevent both negative feelings and feared consequences. In fact, the rituals reinforce the negative thoughts and keep them activated. Finally, intrusions as well as negative feelings are kept alive (Salkovskis, 1985). Contemporary cognitive models have integrated additional OCD-typical beliefs like the overestimation of threat, the need to control thoughts, the intolerance of uncertainty, and perfectionism (OCCWG, 1997). Research has shown that (1) these beliefs are correlated with symptom expression, (2) experimental manipulations of the beliefs affect symptoms, and (3) symptom relief after cognitive-behavioral treatment also weakens OCD-typical beliefs. Factor-analytic studies confirmed three correlated belief domains, namely (1) perfectionism and intolerance of uncertainty, (2) overimportance of thoughts, and (3) inflated responsibility and overestimation of threat, together with a general factor explaining the largest amount of variance. It should be noted, however, that OCD-related dysfunctional beliefs are present only in a minority of patients and, therefore, are neither necessary nor sufficient conditions for OCD development. In sum, contemporary cognitive models consider an important part of psychological alterations implicated in OCD, but they

probably overestimate the contribution of cognition to symptom generation. Also, the origins of the biased beliefs remain open up to now.

Brain Circuitry

Progress in brain imaging techniques and findings in brain-lesioned patients have fostered concepts of OCD as a brain disorder with typical anatomical, functional, and connectivity alterations. Descriptions of patients with circumscribed lesions in the basal ganglia or neurological conditions like Huntington disease or Sydenham chorea revealed enhanced prevalences of OC symptoms. This observation gave rise to the conjecture that basal ganglia structures are the brain loci where OCD is mediated or even caused. Since the basal ganglia are part of brain circuits also encompassing the thalamus and subregions of the prefrontal cortex, the neuroanatomical model was extended to the cortico-striato-thalamo-cortical (CSTC) hypothesis of OCD generation (Saxena et al., 1998). In brief, imbalance of a direct and an indirect path within the circuit is assumed to set the course for enhanced activity in the orbitofrontal cortex, the ventral striatum, and the medio-dorsal thalamus. A wealth of brain imaging studies aimed at examining this hypothesis and its extensions. Results moderately support the model (de Wit et al., 2014) showing volume reductions in gray and white matter of the dorso-medial prefrontal cortex, the anterior cingulate cortex, the inferior frontal gyrus, and the anterior insula. Interestingly, altered neuroplasticity with increasing age of patients was detected in this large-scale analysis, with orbitofrontal-striatal regions being more preserved in higher-aged OCD patients, and a relative loss of limbic and paralimbic regions with increasing age. Functional brain imaging studies addressing hemodynamic patterns were also not fully consistent. A voxel-level meta-analysis of functional magnetic resonance imaging findings identified alterations in orbitofronto-striatal, lateral frontal, anterior cingulate, middle occipital and parietal cortices, and the cerebellum (Menzies et al., 2008). This highlights the need to implicate regions outside the classical CSTC areas to develop a comprehensive brain model of OCD. Recently, detection of abnormal interregional connectivity of CSTC regions as well as of cortical hubs, i.e., regions displaying a high degree of connectivity has gained more attention. OCD patients free of medication were reported to have greater distant connectivity in the orbitofrontal cortex and subthalamic nucleus, and greater local connectivity in the orbitofrontal cortex and the putamen (Beucke et al., 2013). The methods to analyze connectivity are under further development, but certainly promise more detailed insights into altered brain dynamics underlying psychopathological conditions. Thus far, studies were cross-sectional, and do not allow deciding whether the brain abnormalities are mere correlates or may qualify as vulnerability markers for OCD and other mental disorders.

Neuropsychological Deficits

As a consequence of brain abnormalities, impairments in cognitive and affective functions mediated by these altered brain areas can be expected. Those impairments are then assumed to contribute to the emergence of OCD symptoms. This neuropsychological deficit model has been widely studied. In a meta-analysis on 115 cross-sectional investigations, small to medium-size performance reductions of OCD patients compared to healthy control persons were found. Domains with effect sizes above 0.5 were nonverbal memory, set shifting/cognitive flexibility, and processing speed. Slightly smaller deficits were detected in response to inhibition and sustained attention (Abramovitch et al., 2013). The small effects suggest that moderators are likely, such as symptom expression on specific dimensions, which have been infrequently assessed in previous studies. Support for the role of neuropsychological deficits as vulnerability markers was provided by a longitudinal study showing that deficits in visuospatial, visuoconstructive, and visuomotor skills at age 13 were identified in individuals who had developed OCD at age 32.

Cognitive-Affective Processing

Several putative cognitive and affective mechanisms of OCD symptom development have been investigated using experimental approaches. For example, extinction learning is the core mechanism assumed to underlie the effects of behavior therapy (see Classical Conditioning Methods in Psychotherapy). Deficits in extinction learning, reflected by reduced activation of the ventromedial prefrontal cortex during extinction learning and skin conductance responses indicative of impaired extinction recall, have been demonstrated in OCD patients (Milad et al., 2013). Another promising area of research is processing of feedback. OCD patients are more sensitive to negative feedback in association learning tasks, and show inhibitory deficits after being punished (Endrass et al., 2013).

Endophenotypes

The search for the so-called endophenotypes or intermediate phenotypes is motivated by the goal to find the missing links between the clinical phenotype and its distal genetic or environmental causes. Endophenotypes are understood as more proximal products of the causes (e.g., genes) compared to clinical diagnoses. While diagnoses involve heterogeneous syndromes and have only limited biological validity, endophenotypes are thought to be biologically more homogeneous and closer to their causal underpinnings. Therefore, they might also help to successfully discover relevant susceptibility gene variants or environmental risk factors for disorders. They are also hoped to elucidate mechanisms of symptom generation and to identify individuals at risk for a disorder. Endophenotypes can be delineated at different stages of the pathogenetic pathway, including genetic, molecular, neurochemical, brain anatomical, large-scale neurofunctional, neuropsychological, information processing, cognitive-representational, and affective levels. To qualify as an endophenotype, a variable must be under genetic control and needs to be associated with the disorder or its symptoms. In addition, unaffected family members of a case proband must show higher rates of the endophenotype. Several candidates have been proposed as endophenotypes of OCD.

Probably, the most elaborate one is an EEG marker of error processing, termed the error-related negativity (ERN)

(Manoach and Agam, 2013). It is replicably enhanced in OCD patients, and twin studies confirmed heritability. In addition, its source lies in the anterior cingulate cortex, a region structurally and functionally altered in OCD; the amplitude is independent of symptom severity changes, and can be reliably measured; preliminary association studies revealed altered genes for the dopaminergic and the serotonergic system; and, importantly, in a family study, unaffected relatives of OCD cases showed enhanced ERN amplitudes (Riesel et al., 2011).

Other candidate endophenotypes are platelet serotonergic markers of central serotonergic functioning, white matter abnormalities in frontal brain regions, functional brain activation patterns during performance of reversal learning and response inhibition tasks, and performance deficits in motor inhibition and in set shifting tasks. These measures indicate executive function capacities that are relevant in the context of the CSTC model (Mataix-Cols and van den Heuvel, 2012). However, most studies were conducted in small samples, and replication of the central findings is necessary.

Need for Integrative Models

Obviously, most models take a selective view on the relevant factors underlying OCD. This is understandable in terms of feasibility issues, both for research and practical transfer. However, only relatively small amounts of variance can be explained by the factors within each model. Therefore, models taking a more integrative view are mandatory for further progress in the field. Using structural equation modeling of data from a twin sample, Taylor and Jang (2011) found evidence for a model, which assumed that genetic and environmental factors influence beliefs and OC symptoms and that beliefs also influence symptoms. Such biopsychosocial models hold promise to reconcile data from different research domains, will set the stage for a more realistic and comprehensive understanding of OCD, and may ultimately improve treatment of the disorder. Multilevel approaches are also needed in endophenotype research when trying to model the complex network of causes, influences, and moderators of processes involved in the generation of OC symptoms. A transdiagnostic, dimensional perspective, which detaches itself from fixed diagnostic categories may be helpful in this process.

Treatment

Natural Course and Placebo Response

OCD is a relatively chronic and persistent disorder, but waxing and waning of symptoms can be observed. Full or partial remission over at least eight consecutive weeks is achieved in only one-fourth of cases within an observation period of 2 years according to a prospective study conducted in a treatment-seeking sample with long illness duration. In a long-term follow-up study over 40 years, 20% of patients experienced full, and further 28% partial remission. That study was initiated before the advent of effective treatments (Skoog and Skoog, 1999). Evaluation trials of selective serotonin reuptake inhibitors (SSRIs) and clomipramine have used pill placebo to control for short-term symptom change due to treatment expectation and general attention effects. Placebo effects in terms of percent change of symptom severity over treatment periods of 4–12 weeks were in the 5–10% range on average, which is clearly less than in anxiety and depressive disorders. In conclusion, OCD is a disorder, which is quite resistant to spontaneous remission.

Empirically Supported Treatments

Cognitive-Behavioral Psychotherapy (CBT)

CBT for OCD is based on behavioral and cognitive models of this disorder (see above). ERP and cognitive techniques are the core elements of CBT. ERP teaches patients to expose themselves to feared stimuli and thoughts, and also to prevent passive and active avoidance strategies. Repeated exposures lead to habituation of anxiety and distress, and patients make corrective experiences regarding the actual degree of dangerousness of situations previously associated with aversiveness. Cognitive techniques promote modification of biased and dysfunctional beliefs by discussing, testing, and modifying them. The great majority of studies on the efficacy and effectiveness of psychological treatments have referred to this type of intervention. More than 15 randomized controlled trials (RCTs) have been conducted, and meta-analyses (e.g., Olatunji et al., 2013) provide strong evidence for reliable and high effect sizes (in the range of 1.0–1.5) for CBT compared to placebo, wait list, or active control treatments. Treatment effects appear to be stable in the majority of cases up to several years but sufficient follow-up data is currently lacking. CBT in OCD appears to show better efficacy compared to other anxiety disorders and depressive disorder. Nevertheless, about 40–60% of patients do not respond sufficiently, due to premature dropout, noncompliance with exposure work within and between sessions, or to residual symptoms and impairments despite adhering to the therapy protocol. In addition, a substantial proportion of patients are not willing to enter CBT due to its demanding and sometimes stress-evoking nature. Patients' adherence to ERP is one of the best predictors of outcome. Consequently, experts have proposed incorporation of specific interventions focusing on motivation and adherence in CBT programs. Preliminary studies suggest that motivational interventions improve outcome and reduce dropout rates. CBT is also successful in children and adolescents with similar effect sizes as in adults. Treatment techniques in young OCD patients are basically the same as in adults, but procedures have to be adapted to the developmental level. Both in youth and in adult OCD, effectiveness studies have confirmed the high usefulness of CBT, also in unselected patient samples and in routine clinical practice outside academic research centers. The format of interventions appears to be less important according to currently available data. CBT in groups has been shown to be similarly effective as in the individual setting, and both intense (daily sessions) and more widely spaced (weekly) formats can be effectively used (Franklin and Foa, 2011). Recently, the so-called third-wave psychotherapies like acceptance and commitment therapy and mindfulness-based cognitive therapy have been proposed as complementing treatment strategies. Preliminary evaluations revealed positive effects, but more controlled trials are necessary. Training protocols such as cognitive bias modification and meta-cognitive therapy have been developed and show some success in changing typical

interpretation biases of nonclinical individuals with OC symptoms. Attention training using a modified probe detection task designed to direct attention to the location of contamination-related words resulted in improved approach to feared objects. Further adaptation of these interventions to clinical needs is required.

Pharmacotherapy

Clomipramine, a nonselective serotonin reuptake inhibitor, was the first drug shown to be efficacious in reducing symptoms of OCD in controlled trials. Later, SSRIs fluvoxamine, fluoxetine, sertraline, paroxetine, and citalopram have been established as standard pharmacotherapy, mainly due to their slightly more favorable side effect profile. The effect size in RCTs amounts to 0.9 on average in adults, which is somewhat lower than that of CBT. In adolescents, treatment response is less impressive, with an average effect size of about 0.5. The most relevant disadvantage of pharmacotherapy with clomipramine or SSRIs is the high relapse rate after discontinuation of the medication, which necessitates maintenance of treatment or very slow tapering of the drugs. Pharmacological augmentation strategies aimed at addressing partial or even complete nonresponse to SSRIs or clomipramine have been proposed and evaluated. Augmentation with atypical neuroleptics, in particular risperidone, yielded more additional responders than adding a placebo but still only one-third of partial or nonresponders will sufficiently improve then. Potential adverse side effects have to be taken into consideration and may increase the risk to benefit ratio. Patients with comorbid tics or with schizotypal personality characteristics have been suggested to be the target population, which is most eligible for this augmentation strategy. There is no sufficient evidence for the efficacy of other pharmacological agents and for the use of second-generation antipsychotics as monotherapy. Antiglutamatergic agents like riluzole, memantine, or ketamine are in the early phase of evaluation and require further study (Fineberg et al., 2012).

Combination of Psychological and Pharmacological Treatments

While CBT can be considered as the first-line treatment of OCD in terms of its superior efficacy and safety, combined treatment with CBT and SSRIs or clomipramine is often recommended. There is little evidence for an additive effect of medication in excess of the CBT effect in OCD patients presenting with low comorbidity. However, highly depressed OCD patients might need antidepressant medication before being able to fully benefit from CBT, and pediatric OCD patients with ADHD comorbidity will also have better results when comorbid symptoms are targeted with adequate pharmacotherapy. Pharmacotherapy as a single treatment, conversely, is not fully adequate in the majority of cases since efficacy is limited, and relapse rates are high after discontinuation. CBT should be added if available and accepted by the patient. Thereby, relapse rates can be lowered and more remissions can be achieved (Franklin and Foa, 2011).

A pharmacological augmentation strategy with a different approach is the administration of D-cyloserine, a partial glutamatergic N-methyl-D-aspartate agonist, before each ERP session to enhance learning processes. D-cycloserine, originally developed as an antibiotic effective against *Mycobacterium tuberculosis*, has no psychotropic effect on its own, and is also not known to elicit adverse effects with the dosages used. Preliminary studies in small samples have been promising but further research is needed before implementation of this strategy in routine care.

Brain Stimulation and Psychosurgery

The efficacy of repetitive transcranial magnetic stimulation in OCD has been evaluated in several pilot trials with mixed success. Improvement of the protocols might result in more reliable effects.

Deep brain stimulation (DBS) of the nucleus accumbens via implanted electrodes has been developed as a last resort intervention for treatment-refractory patients with severe symptoms and impairments. The technique is invasive and therefore controversial, but complications and adverse events are relatively rare. Preliminary results from controlled studies are promising (Denys et al., 2010), showing about 50% improvement in symptom severity, and a 25% difference between active and sham stimulation. To make DBS useful for clinical routine, more evaluations of short- and long-term effects are needed. DBS obtains its convincibility from directly targeting brain structures assumed to be involved in the development of OC symptoms.

Care and Guidelines

Although efficacious therapies exist, many patients cannot benefit from them due to their limited availability. CBT, for example, is not provided in many regions, even not in highly developed industrial countries. If available, waiting time for beginning a CBT program may be several months. Sometimes, training and supervision of therapists are not optimal resulting in procedural shortcomings of provided CBT. For example, ERP is not conducted in many therapies described as cognitive-behavioral. This example makes clear why it is important to provide knowledge updates regarding empirically supported therapies to health care providers. To foster dissemination of this knowledge, practice guidelines have been developed (e.g., NICE, 2005). They give recommendations for therapy options that are graded according to their level of evidence. Global statements as well as such addressing specific subpopulations and problems are traceably derived from empirical studies. Nevertheless, the development of practice guidelines must be complemented by serious efforts to bring the guidelines to practitioners and to attain their acceptance.

Outlook

Theory and treatment of OCD have dramatically changed over the last decades, and the disorder is in the focus of contemporary research. Both the subjective and the socioeconomic burden of OCD have been acknowledged. We have efficacious psychological and pharmacological interventions at hand, but there is room for improvement in terms of success and dropout rates. To achieve such progress, more research into the mechanisms of symptom development and change must be conducted. Dimensional symptom description might help in identifying specific origins and interventions for different symptom expressions. Relatively less knowledge exists about

OCD in childhood and its role for the course of disorder in adulthood. Moreover, OCD in old age is underrecognized and deserves more attention. More refined etiological models involving endophenotypes have the potential to bridge the gap between pure psychological and pure biological approaches in future research. A major challenge will be the realization of prospective longitudinal studies to track developmental aspects of symptom generation and maintenance. Furthermore, efforts to establish international consortia for collection and analysis of large-scale data samples, for example from brain imaging and genetic research, have to be intensified. Such projects might overcome statistical power problems for testing factors with small effects and allow for the development of more complex and realistic models of the disorder. A translational research perspective and increased efforts to disseminate the knowledge gained from basic and intervention research will ensure that progress in the field will ultimately arrive at the patient.

Occipital Lobe (Visual Cortex): Functional Aspects

Oliver Braddick, University of Oxford, Oxford, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Several aspects of structure and function of the occipital lobe provide insights into the mechanisms of visual perception. The occipital lobe includes the primary visual receiving area (V1), which is laid out as a retinotopic map of the visual field, allowing signals from neighboring parts of the visual field to interact, and the first functional convergence of signals from the two eyes takes place on neurons in V1. V1 neurons show responses, which are selective for various stimulus properties, including orientation, spatial frequency, direction of motion, binocular disparity, and color. Neurons that respond to similar stimuli are arranged in 'columns' running perpendicular to the cortical surface, which form a complex regular structure.

Areas V1 and V2 act to segregate three different kinds of visual information: color, spatial pattern, and motion in interleaved structures ('blobs' in V1 and 'stripes' in V2). This segregation of information serves as a starting point for the distribution of visual information to a hierarchy of multiple cortical areas, each with its own topographical map of the visual field and a degree of specialized function. The properties represented by neuronal activity become progressively more complex and global in higher areas, and progressively less localized. While these areas are hierarchical and divided between 'dorsal' and 'ventral' processing streams, there are rich interconnections between areas, as well as feedback pathways by which areas higher in the hierarchy can modulate the activity of lower areas. All these systems become functional early in postnatal life, and their early development is initially highly plastic.

The Occipital Lobe

The occipital lobe, at the back of the brain, is one of the four lobes into which each cerebral hemisphere is conventionally divided. The lobes are defined purely by anatomical landmarks, not functionally. However, the occipital lobe has a certain functional unity in that, so far as we know, the whole lobe is primarily concerned with processing visual information. How this processing works at the neural level, and how it is organized structurally, provides some insights about the mechanisms of visual perception (*see* Visual Perception, Neural Basis of). Much of this knowledge has come from studying the occipital lobe of the macaque monkey, but human neuroimaging studies have become increasingly detailed in recent years and have shown that the human and macaque occipital lobes are closely similar in many respects, containing multiple areas which represent visual information in the field of view. It is now clear that this array of areas also extends into the temporal and parietal lobes, with some areas spanning the notional boundaries between lobes, reinforcing the idea that these boundaries do not have detailed functional significance.

These areas maintain a basic spatial organization of visual information, but also extract and organize visual attributes such as local shape, motion, color, and depth. To understand this organization, it is important to appreciate that processing goes on in the cerebral cortex, a thin, folded sheet of tissue across which distinct and specialized visual areas are laid out, but also that the cortex is layered, with different layers containing a characteristic pattern of connections providing inputs and outputs of information to and from each area.

The Retinotopic Projection to Area V1

The fibers delivering visual information to the cerebral cortex terminate in a region around the occipital pole of each hemisphere, known as striate cortex, primary visual cortex, or area V1. Each incoming fiber, and each individual neuron in V1, carries information about a specific small region of the visual field (its 'receptive field'). These receptive fields are arranged in an orderly way across the cortex, so that neurons with neighboring receptive fields are close together. Overall, area V1 in each hemisphere is laid out like a spatial map of the opposite half of the field of view (*see* Topographic Maps). The field is split, with the right half-field represented in the left hemisphere, and vice versa. In this map, the vertical midline of the field is represented furthest back, near the occipital pole, and moving forward across the medial surface of the cortex corresponds to moving horizontally outward in the field of view. This orderly 'retinotopic' mapping must be functionally important, presumably because it allows neurons serving nearby field locations to interact readily. Several functions for such interactions can be suggested. First, to reliably represent local visual properties, such as the orientation of edges, requires information to be gathered and compared across cells representing a local area of the visual field. Second, local connections with a regular organization between cells can serve to link the features that form spatially connected objects, for example, adjacent parts of an object's outline. Third, connections linking nearby field regions may be critical in the development of cortical function, exploiting the statistical associations between the stimulation received from adjacent parts of the scene to build functional units that are well tuned to the structure of the visual world.

The exception to the rule that nearby locations in the field are represented close together in the cortical surface is provided by the division between hemispheres at the vertical midline. 'Local' connections across the midline have to be provided by long fibers that cross between hemispheres in the corpus callosum. Despite this, it is striking that our subjective impression of the visual field is quite seamless at the midline, and the

division between hemispheres has few if any functional consequences in normal individuals.

The scale of the retinotopic map is not uniform. The cells of the central retina are much more densely packed than in the peripheral field, and so provide much more information per unit area. This variation in information is reflected in a variation of the 'magnification factor' in V1, with a much larger area of cortex devoted to the central region than to the same area in a peripheral region. In this way, cortical organization provides the greater processing power needed for the fine detail and spatial precision of central vision. This principle extends to 'extrastriate' visual areas beyond V1, although the quantitative relationship between cortical 'magnification' and area of tissue varies between areas.

Binocular Organization

An important function of area V1 is that it provides the first point in the visual pathway where information from the two eyes can be integrated. The fibers from each eye are segregated into alternating bands ('ocular dominance stripes') as they arrive in layer 4 of cortical area V1 (see Section Columnar Organization). The first real interaction between left- and right-eye signals occurs when these fibers converge on cells in the layers above layer 4 (Hubel, 1988). This interaction allows both eyes to contribute to a unified visual representation of the world. It also allows neurons in V1 and beyond to register the disparity between the two eyes' views, which serves as the basis for stereoscopic depth perception (Parker, Chapter 49 in Chalupa and Werner, 2004).

Stimulus Selectivity of Cortical Neurons

The number of neurons in area V1 is at least a 100-fold greater than the number of input fibers. This enormous information-processing resource means that V1 does not simply map the visual input: it can also transform it. Each local region of the visual field is represented by an array of neurons, with each neuron responding selectively to a particular type of stimulus (Hubel, 1988). Most V1 neurons respond to contours, and are selective in several, if not all, of the following respects:

- strongest response to a preferred orientation of the contour, with response falling off as the angle is further from this optimum ('orientation tuning');
- a preferred type of contour: light bar, dark bar, or edge;
- a preferred spatial scale, so that the cell may respond either to the broad pattern of light and dark, or to fine detail ('spatial frequency selectivity');
- stronger response to one direction of motion than for the opposite direction;
- differences in binocular balance: some cells respond predominantly to the right eye, some to the left, and some only give their best response when both eyes are activated together. In the latter, binocular group, cells may be selective for stereoscopic depth, i.e., they respond best to objects that are either nearer, farther, or close to the distance on which the eyes are converged; and
- color, with one range of wavelengths preferentially activating the cell and another inhibiting it (sometimes combined with an enhanced response to color contrast).

This array of differently tuned neurons means that the cortex can represent all these diverse properties according to which particular pattern of neurons is active (a population-based 'place code'; *see* Visual Perception, Neural Basis of).

Columnar Organization

Retinotopic mapping (Section The Retinotopic Projection to Area V1) implies that within a small region of V1, all the cells deal with a local region of the field of view. The cortex also has a finer-grain spatial organization, reflecting the differences in tuning described in Section Stimulus Selectivity of Cortical Neurons. Connections between neurons are predominantly vertical (i.e., perpendicular to the cortical surface). Presumably as a result of these connections, neurons in a vertical column have similar response properties. In particular, there are columns of cells responding to the same orientation, and broader columns within which a particular eye predominates. The combination of these two forms of organization has led to the idea of the 'hypercolumn,' a module of visual cortex that includes a complete representation of both eyes' inputs and all possible orientations, for a particular local region of the visual field.

From column to column, there is also a spatial ordering; in a horizontal track across V1, the preferred orientation changes in an orderly sequence. As with the retinotopic organization, this order means that a regular, local pattern of connectivity between cells creates communication between cells responding to contours with the same or similar orientation, supporting the integrative processes discussed in Section The Retinotopic Projection to Area V1.

Thus, at the fine scale, cortical layout is not purely a retinotopic map. However, both retinotopic and orientation-based mapping mean that orderly spatial connectivity between cells can establish communication between cells responding to similar stimuli. The columnar organization has been described here for V1, but it is believed to be a general principle that applies also to the extrastriate areas described in Section Specialized Extrastriate Areas, and indeed to cortical organization more widely, including the representation of other sensory modalities besides vision.

Modern methods of optical imaging allow the array of neurons that respond to a particular stimulus to be highlighted, and so the spatial layout of the orientation columns can be visualized. It turns out that they are not so much columns as bands that converge at 'pinwheels,' so that the representation of contour orientations around the clock is arranged in a path around the pinwheel center. Motion responses also enter the organization: neurons responding to a particular contour orientation (e.g., vertical) may be selective for either of two opposite motions of the contour (e.g., leftward or rightward); there is a sharp discontinuity between regions of the two types, and these lines of discontinuity connect pinwheel centers. Another, related, organization is a periodic pattern of 'blobs' showing a high concentration of the metabolic enzyme cytochrome oxidase (CO), that can be revealed anatomically by staining cortical tissue. These blobs

contain many color-sensitive cells and little specificity for orientation. Overall, there appears to be an elaborate, repetitive, crystalline order to the functional selectivities of cortical neurons. Many details of this ordering are not yet understood, but it must be a key to understanding the circuits that define visual cortex function, and how these are constructed in development.

Interleaved Pathways through V1 and V2

The visual pathway leading to V1 in fact includes two major subpathways, and this division runs through processing in V1 and beyond (Daw, 2012). One group of cells, the magno cells, have large receptive fields, fast responses, and do not carry information about the color of light. The parvo cells, in contrast, respond less well to rapidly changing stimuli, but better to fine spatial detail, and are wavelength-selective (e.g., activated by one range of colors and inhibited by others). These two classes of cells appear to separate the information useful for detecting motion on the one hand, from that required for fine detail and for color vision on the other. Correspondingly, the perception of motion and of color seem to work largely independently of each other.

This division is maintained in the cortex. In V1, the fibers of magno cells terminate in a distinct layer (4B) containing many motion-selective cells. Within the parvo input, color-specific information is also anatomically separated into the CO 'blobs' described in Section Columnar Organization. Thus, in the fine structure of area V1, three different kinds of processing are segregated but interleaved: motion information in layer 4B, color information in the blobs, and spatial pattern (orientation) in the 'interblob' regions.

V1 sends information to a neighboring area, V2, which forms a second retinotopic map. The three types of visual information interleaved in V1 are kept segregated in V2, into three parallel sets of stripes that send their output to different extrastriate areas (Section Specialized Extrastriate Areas). Thus, apparently a major role of areas V1 and V2 is to marshal different kinds of information into separate cortical processing streams.

Specialized Extrastriate Areas

V1 and V2 are only two of what are now recognized to be a large number of distinct cortical visual areas forming an interconnected hierarchy (Zeki, 1993). Further forward in the occipital lobe, most of the lobe can now be divided into a mosaic of areas, referred to as 'extrastriate' since they lie outside the primary striate area. These areas can be distinguished by

- mapping: each area (at least at the lower levels of the hierarchy) forms a distinct, complete retinotopic map of the visual field;
- connectivity: there is an orderly set of projection fibers connecting one area to another and preserving the retinotopic mapping. Connections with 'higher' and 'lower' levels in the hierarchy are made by different cortical layers, which allow the hierarchical structure to be defined; and
- function: each area has a characteristic balance in the type of stimulus selectivity found in its neurons (e.g., color selectivity common and directional motion selectivity rare, or vice versa), leading to the idea that different areas have distinct functional roles in vision.

This functional division of visual areas was first suggested from recordings of the responses of single neurons in macaque cortex. More recently, it has been explored in the human brain by functional magnetic resonance imaging (fMRI; *see* Cognitive Neuroscience; Eye Movements in Reading) (Wandell and Winawer, 2011). Imaging allows areas to be defined by their retinotopic maps, and also by the specific visual properties that activate them (e.g., one area is activated best by color differences, a different area by coherent motion in the visual field). This idea of functional localization fits with findings in some patients with brain lesions, who show a deficit limited to one specific aspect of vision (e.g., a loss of just color or just motion processing).

The main areas that can be identified as retinotopic maps have been labeled as V3, V3A, V4, and V5 (**Figure 1**). Together they form a third tier (or possibly, third and fourth tiers) of a processing hierarchy beyond V1 and V2. Area V5, also known as MT ('middle temporal,' although this does not accurately describe its location in humans or macaques), lies on the boundaries of the occipital and temporal lobes in the human brain. V5 has been especially intensively investigated because it has a very well-defined specialization for processing motion information. At the same level in the macaque cortex, but complementary in its specialization, is area V4, which has the highest proportion of color-selective neurons, a type of selectivity almost absent in V5. Macaque V4 also shows processing of more complex aspects of spatial pattern than those found in V1 and V2 neurons.

Areas V4 and V5 represent a further stage in the segregated streams of processing found in V1 and V2 (see Section Interleaved Pathways through V1 and V2), with V5 as the destination of the motion information derived from layer 4B of area V1, and V4 receiving the color and form information derived from the blobs and interblob regions. Many V5 cells encode stereo disparity as well as motion, in a way that allows their combination to give information about the 3-D layout of the environment and the observer's motion through it. The functional distinctions between V4 and V5 are an aspect of the broader division between 'dorsal' and 'ventral' cortical streams (Daw, 2012) (*see* Visual Streams: Dorsal and Ventral). The dorsal stream consists of areas carrying motion and spatial information to the parietal lobe, where it provides the visual basis for controlling actions. The 'ventral' stream carries pattern and color information required for the identification of objects in the temporal lobe.

Functional anatomy, then, supports a view that the visual process is based on distinct modules with different functions; in particular, that there is a broad separation of the modules which tell us 'what' object we are looking at, from those that tell us 'where' or 'how' we can act upon it.

Evolution of Occipital Lobe Organization

It is clear that the same division between the streams exists in human as in monkey cortex, but some important details are

Figure 1 Distinct visual areas in the occipital lobe, revealed by fMRI mapping of visual field representations (from Wandell, Brian A., Winawer, Jonathan, 2011. Imaging retinotopic maps in the human brain. Vision Research 51, 718–737 by permission). The upper left figure illustrates the view of the outer (lateral) surface of the right cerebral hemisphere; the lower right shows the medial surface (which faces the other hemisphere across the midline). V1 (red) is the first visual area where the input fibers of the optic radiation arrive. Areas V2 and V3 have separate ventral (v) and dorsal (d) sections, mapping the upper and lower halves respectively of the visual field. V3A and V3B are distinct areas with their own maps, which despite this notation are not parts of V3. 'hV4' refers to human V4, 'LO-1 and LO-2' to maps of the field within the lateral occipital complex. 'TO-1, TO-2' denote maps in the temporal/occipital area identified by the authors, which are included within the motion-sensitive area MT+ (otherwise known as V5). The functional distinctions between these areas, and their interconnections, are discussed in the text. 'IPS,' 'CoS,' 'FG,' 'OTS,' and 'CalS' refer not to functional areas but to anatomical landmarks: intraparietal sulcus, collateral sulcus, fusiform gyrus, occipito-temporal sulcus, and calcarine sulcus, respectively.

different (Sereno, 1998; Van Essen, chapter 32 in Chalupa and Werner, 2004). Because of the great expansion of frontal cortex in humans relative to monkeys, the visual areas occupy a smaller percentage of the area of the human brain, but their absolute area is still several times greater than in the macaque monkey. Some areas in the human occipital lobe do not seem to have a direct correspondence with the monkey's organization. For example, human neuroimaging reveals a prominent lateral occipital area (LO), which responds much more strongly to the image of an object than to a scrambled version of the same object, and is presumed to be an important component of the ventral-stream network that enables us to recognize objects. Such an area has not yet been recognized in the monkey brain. The relation between color sensitivity and retinotopic mapping, found in monkey V4, seems to involve a more complex set of areas in the human brain. In the dorsal stream, the anatomy and connectivity of area V3A seems similar in both species, but in humans this area is highly motion-sensitive, whereas in the monkey it responds to stereoscopic depth but not particularly to movement. It is now possible to carry out closely analogous measurements using fMRI brain imaging in each species, and future studies with this method should reveal how the functional organization of the human occipital lobe has evolved.

Spatial Generalization, Functional Specialization, and Global Processing

Until recently, it was believed that retinotopic organization was limited to the areas V1–V5 described above, and that this feature was lost in further levels of the presumed hierarchy, such as LO area. Advances in imaging methods have led to revisions of this view, so that for instance LO has now been shown to consist of two areas each with its own retinotopic map. Nonetheless, it remains true that spatially precise mapping becomes a less dominant principle as we ascend the processing hierarchy. For example, within the dorsal stream, the directionally selective cells in area V1 have quite small receptive fields; near the center of the visual field these may span an area less than 1° across, while the receptive field size of

V5 cells in the same location is 4–5 times larger. A group of V1 cells are believed to provide subunits, which combine to yield the larger motion-sensitive area in V5. V5 cells in turn provide the inputs to cells in the nearby area MST ('medial superior temporal,' no specification of its location in humans or macaques), whose receptive fields are so large that they may extend into the opposite half of the visual field. Directional neurons in V1 represent motion in a very local region of the field; the increase in receptive field size in V5 and MST provides the basis for analyzing more global properties. Thus V5 neurons are highly sensitive to the coherence of motion direction over an extended region, and in turn MST cells combine V5 signals to detect the wide patterns of optic flow across the retina which occur as a result of the observer moving through the environment. Similarly global properties, but related to static pattern rather than large-scale motion, are represented in V4 and higher areas of the ventral stream.

There is a second potential reason why higher levels of the cortical hierarchy should show increasing receptive field size and coarser, or absent, retinotopic mapping. The recognition of an object should not depend on it being in a particular location but, rather, requires generalization across the visual field. Thus a neuron which plays a part in such recognition needs to gather information across a large spatial field.

In both dorsal and ventral streams, it seems to be a general principle that as visual information is progressively transformed and elaborated in the brain, the less relevant is retinal location for the way in which it is represented.

Development and Plasticity in the Occipital Lobe

In normal human development, the functions of occipital cortex are rudimentary at birth, and the visual behavior of newborn babies is largely controlled by neural networks in subcortical brain structures. However, in the first year of life very large numbers of synaptic connections are formed. This increasing connectivity allows the special functions of visual cortex to emerge: in the first 3–4 months orientation selectivity, directional selectivity, and binocular interaction develop in sequence, and global processing in extrastriate areas contributes to infants' visual abilities soon afterward (Braddick and Atkinson, 2011).

The emerging structural and functional organization of visual cortex do not follow from a rigid genetic wiring diagram, but result from the interplay of an intrinsic ground plan with the neural activity stimulated by visual experience. The most studied aspect of this is the interaction between signals from the two eyes (Section Binocular Organization) (chapters 4 and 12, Chalupa and Werner, 2004): if one eye is deprived of vision, that eye starts to lose its connections to area V1, the ocular dominance bands for that eye shrink and those for the other eye expand. This plasticity of cortical connections produces the phenomenon of amblyopia, or 'lazy eye,' in children who suffer an early imbalance between the eyes (for instance, if one eye is very long-sighted). Recent brain imaging studies have shown that even more radical reorganizations of the visual cortex are possible. For example, in an infant for whom one half of the brain is seriously damaged around birth, the map in the visual cortex can be completely rearranged so that both halves of the visual field are represented in the intact cerebral hemisphere. This plasticity is not restricted to the single sense of vision: functional imaging shows that in individuals who have been congenitally blind (but not in late-blind or sighted people), the visual occipital cortex is activated when they are reading Braille, implying that the sense of touch has in part taken over an area that is usually visual. All of these changes in the brain require the anomalous sensory input to take place in early childhood, supporting the idea of a 'critical period' in which brain networks can be adapted to the pattern of input, before neural connections become set. Research has found that dorsal stream functions are much more disrupted in developmental brain disorders than those of the ventral stream, but the neural basis for this 'dorsal stream vulnerability' is not yet understood.

Recurrent and Top-Down Influences

While it is clear that the visual areas can be ordered into a hierarchy, the flow of information is not simply upward from the lower levels. Almost every connection from a lower to a higher area has a corresponding connection in a reverse direction. Thus, in the neural structure, there exists the potential that low-level processing, e.g., in V1 and V2, does not run simply automatically, but is controlled and directed by top-down processes. There is also the potential for recurrent loops, by which information is exchanged between lower and higher areas and progressively refined. Such loops mean, for instance, that although the primary response of V1 neurons is to local features of the visual pattern such as an edge segment, these responses can be influenced by the global structure of the scene, such as whether the edge is on the left or right of an object (Lamme, chapter 45 in Chalupa and Werner, 2004). And although the different cortical modules have distinct functions, there are rich interconnections between them at the same level, including connections between dorsal and ventral streams. Occipital cortex is a modular system, but one in which the modules closely interact to produce integrated visual perception.

Top-down influences on occipital areas can also come from further afield in the brain. The decision to attend to one particular region of the field of view activates the corresponding part of the retinotopic maps in area V1 and elsewhere, acting to amplify the response to stimuli in the attended region (Kastner, chapter 101 in Chalupa and Werner, 2004). The effects of attention are not limited to sensitizing one area of space; for example, if a particular judgment is required, say of color or of motion speed, the visual brain areas responsible for the relevant kind of processing become differentially active. Perception is an active process, not just the passive processing of the visual input, and the occipital lobe participates in this goal-directed activity.

Abstract

In this article a brief historical background of the development of social and psychological working conditions is followed by a description of the presently most widely utilized theoretical models for studying the psychosocial work environment in research and practice, the 'person–environment (PE) fit,' 'demand–control–support,' 'organizational justice' and 'effort–reward' models. Possibilities and difficulties in assessment are discussed. It is pointed out that both 'objective' and 'subjective' aspects are important and that these are not always strongly correlated. Physiological models linking the psychosocial models to health and disease are discussed and finally experiences of interventions are discussed. The main conclusion is that it is possible to define and assess psychosocial factors at work, that such factors are linked to physiological mechanisms, and that interventions based upon them are possible.

Introduction: Work and Health

During historical periods preceding industrialization, most of the work that humans were involved in was unpaid. The borders between work and leisure were not clear. It was with industrialism that paid work started to play such an important role in human life. For several generations, paid work has been the activity that has generated a family's needs for survival.

Health is not only the absence of illness. It is also a positive state in its own right. However, most of the research that has been published regarding work and health has been devoted to the establishment of relationships between certain adverse working conditions and illness. Accordingly, most of this article will be on work–illness relationships. But we shall also discuss possible pathways between good working conditions and the promotion of health.

An important basis for our understanding of the effects of working conditions on health has been the physiological stress research which was initiated by Hans Selye (1976). Initially stress researchers studied acute reactions to energy-demanding situations. Subsequently, they examined the biological consequences of long-lasting adverse life situations.

The Physiological Basis of the Effects of Work on Health

Genetic evolution and selection processes are slow. Therefore our biological reactions to stressful situations are likely to be approximately the same as they used to be several thousand years ago. It has been emphasized by many authors (Levi, 1972; Frankenhaeuser, 1980) that this may not be functional for man in modern societies and especially not at work where physical demands are becoming less and less important. It was functional for the primitive human being who needed to face dangerous animals to become strong, courageous, and insensitive to physical pain. However, most contemporary dangers have to do with complicated social interactions and in such situations the mobilization of physical energy is not functional. It is possible to regard some adverse aspects of lifestyle, such as smoking, the use of drugs stimulating the central nervous system, and the consumption of sweets and alcohol as 'external' efforts to cope with energy-demanding situations.

Energy Mobilization and Anabolism at Work

In Selye's (1976) general adaptation syndrome, 'stress' was seen as the general reaction to a nonspecific challenge or adverse condition. The situation that induced stress was labeled a stressor (factor which induces stress). Since it has central importance to the understanding of stress at work, a short description of energy mobilization will be given here. The most important biological process is the provision of energy – glucose and free fatty acids enter the blood and are used for the immediate production of energy. But there are several parallel phenomena, all of which aid the body in physical fight or flight responses. Examples are lowered excretion of water and salt, decreased sensitivity to pain, and decreased inflammatory responses to infections. Since energy mobilization (resulting in elevated blood concentration of glucose and free fatty acid) has the highest priority, anabolism (restorative and regenerative activities in the cells) is downregulated. Anabolism is central to the body's central defense of all the organ systems that need constant rebuilding and restoration. If this goes on for a long time (several months) increased sensitivity to physical and psychological stress in bodily organs is the ultimate result. There is a balance between regulation of energy mobilization and anabolism. There are two parallel regulatory systems ranging from the hypothalamus to the pituitary and to their respective endocrine organs, namely the hypothalamo–pituitary–adrenocortical (HPA axis) and the hypothalamo–pituitary–gonadal (HPG axis) systems. While the HPA axis facilitates energy mobilization, the HPG axis facilitates regeneration and reproduction. In many situations they counteract one another. For instance, during long periods of excessive arousal and effort the HPG axis is inhibited. But on the other hand, high HPG axis activity may protect the body against the adverse effects of long-lasting, excessive HPA axis activity

(Theorell, 2012). This has importance in the work environment in the sense that the psychosocial processes that stimulate the HPG axis may also protect against adverse effects of a stressful work environment.

Another consequence of long-lasting demands for energy mobilization is that the endocrine systems may change their regulatory patterns. This means that the ability of the body to stop energy mobilization when it is no longer needed may be disturbed or that the counter-regulation (inhibition of energy mobilization) is inhibited. Most processes in the body have a counter-regulatory mechanism that operates in order to inhibit a process that has been stimulated.

Physiological Short-Term and Long-Term Adaptation to Requirements at Work

The HPA axis is of central importance to the biological arousal mechanism. The steroid hormone cortisol which is released from the adrenal cortex is the most extensively studied 'agent' in this system. Cortisol facilitates biological arousal in most organ systems. Disturbed regulation of the HPA axis has been described as a possible consequence of long-lasting arousal. There are at least three kinds of such regulatory disturbances in the HPA axis, all of which are of relevance to health at work:

1. Lack of inhibition of arousal. All reactions in the body evoke counter-regulatory reactions. This is true also of energy mobilization, which should stop when the threat disappears. Normally cortisol inhibits higher centers in the HPA axis when it has been in the aroused state for some time. When this inhibition does not take place in the normal way, the levels tend to become constantly elevated.
2. Lack of response to stimulation of the HPA axis. This means that plasma cortisol levels are low and that normal activation does not take place when the HPA axis is stimulated artificially. This has often been labeled the 'flat cortisol curve.' This refers to the fact that the circadian variation is small and the 'awakening response' (the normal increase in cortisol levels from awakening until half an hour later, which could be regarded as a kind of stress response) is attenuated.
3. Unstable levels. In this kind of disturbance the plasma cortisol levels may be low at rest, but certain situations – that are specific to the individual and have to do with the symbolic significance of the event – trigger a strong HPA axis reaction that may seem to be out of proportion to the importance of the trigger. This occurs in subjects who have been exposed to extraordinarily stressful situations, such as torture, war, disasters, and incest.

The first kind of regulatory disorder (1) is typical of Cushing's syndrome (overproduction of corticosteroids including cortisol due to a disease in the adrenal cortex) and could be one alternative regulatory disturbance in clinically severe psychiatric depression. In patients hospitalized for severe psychiatric depression a pattern with constantly high cortisol levels was observed (Rubin et al., 1987). This pattern has become less prevalent with the frequent use of antidepressive medication in the population. Currently, in epidemiological studies of the relationship between cortisol excretion and depression, it is mostly not observed (see for instance Alderling et al., 2008).

The second kind (2) has been shown to exist in a subgroup of patients with the diagnosis of chronic fatigue syndrome or CFS (Demitrack et al., 1991). Conditions with long-lasting fatigue as a prominent feature, for instance the burnout syndrome, have been shown to be associated with poor awakening response, which is correlated with the 'flat cortisol curve' (Chida and Steptoe, 2009; Halford et al., 2012)

The third kind of regulatory disorder (3) is found in post-traumatic stress disorder (PTSD) (Charney et al., 1993). The key element in the etiology of PTSD seems to be that the long-lasting extreme arousal level increases the number of cortisol receptors on the cell surfaces and also increases their sensitivity. Since the sensitivity is high, only low concentrations of cortisol are needed to keep the system working at rest. This may be the reason why low serum cortisol levels are found at rest in patients with PTSD.

It is important to consider these different forms of regulatory disturbance in working subjects. Men and women with severe such regulatory disturbances are mostly unable to work and mild disturbance causes disturbed ability to cope with working tasks.

Unemployment and Stress

Unemployment is a common phenomenon in all industrialized countries. In most European countries it is presently of the order of 10%. Research has tried to establish the extent to which unemployment contributes to poor health. At present there is agreement that poor health increases the risk of becoming unemployed in periods of financial crisis but there is also agreement that unemployment per se contributes to poor health. Longitudinal studies of subjects who have gone through the different stages of unemployment (Brenner and Levi, 1987) or started activities again after a long period of unemployment have shown that several physiological systems are markedly affected by these processes. For instance, there is elevation of the secretion of cortisol (an index of energy mobilization) and prolactin (which mirrors passiveness in a crisis situation). It is accordingly reasonable to assume that health could be affected. There is published research showing that long-lasting unemployment increases the risk of mental disorder (Hallsten, 1998) and is also associated with a lifestyle that increases the risk of developing cardiovascular disease, particularly in young people (Janlert et al., 1991; Janlert and Hammarström, 1991). Economic hardship may add to the health consequences (Vinokur et al., 1996). Downsizing is associated with increased prevalence of poor mental health (emotional exhaustion and depression) not only for the dismissed workers but also for those remaining as workers in the 'downsized' workplace. A recent study of the situation in Hungary, Sweden, and France showed that the relationship between downsizing and poor mental health is particularly pronounced in Hungary where societal and financial support systems are weaker than in the other studied countries. In addition, studies show that subjects who remain employed after dismissal of colleagues in their workplace may also suffer from mental symptoms and that the way in which

management handles downsizing is crucial for the mental health of the employees (European Commission, 2011). Not unexpectedly, a well-organized downsizing process with good information and understandable goals does not result in as much health deterioration among employees as a chaotic, poorly organized downsizing process resulting in a less effective organization.

Jahoda (1979) formulated the basic reasons why work is such an important activity in modern life – the most central one being that work provides structure to life. There is extensive research showing that organized support can help the unemployed to regain employment (Vinokur et al., 1995). Evaluation of such programs, however, also shows that these programs may increase passiveness and feelings of low self-esteem if the initiative of the individual is taken away.

Combined Effects of Physical and Psychosocial Adversities at Work

Extensive research has been devoted to the disentanglement of physical stress from psychological stress in studies of health and disease. For instance, in the study of the importance of ergonomic load to the development of musculoskeletal disorders, it has been considered important to adjust for psychological stress. Extensive epidemiological studies of large samples of subjects have shown that ergonomic load contributes to the development of musculoskeletal disorder but that psychosocial factors at work may also contribute significantly (Kilbom et al., 1996). It has been shown that combinations of physical ergonomic and psychosocial factors may be of particular importance to low back pain (Vingård et al., 2000). The potential importance of the combination of noise exposure and job strain has also been documented in relation to morning cortisol excretion (Selander et al., 2012). Furthermore there seems to be an interaction between long-term symptoms of prolonged adverse stress (burnout syndrome, see above) and the ability to cope with a combination of acute stress and unpleasant sound, particularly among female working subjects. A study was based upon screening of working subjects with high scores on emotional exhaustion. Emotionally exhausted subjects showed lowered noise thresholds after acute experimental stress whereas normal subjects showed elevated thresholds. In other words, the normal way of coping with a combination of acute stress and noise is to elevate the noise tolerance whereas exhausted subjects become more sensitive to noise when there is acute stress (Hasson et al., 2013).

It has been important for the study of relationships between working conditions and health to have theoretical models that form the basis for hypothesis testing. The interplay between the individual and the environment has been an important point of departure in all theoretical modeling in this field. Some of the models have focused on environmental aspects – for instance, the demand–control and organizational justice models – and some on individual aspects, for instance, the eustress–distress model. The person–environment (PE) fit and the effort–reward imbalance models are other examples of models taking the interaction between the individual and the environment into account. These four models will be described briefly below.

Theoretical Models for the Study of Work and Health – Individual or Environment

The individual's response to demanding work situations has been the point of departure for Frankenhaeuser and her coworkers (Frankenhaeuser, 1980) who introduced one of the most influential models, the eustress–distress model. According to this model, the individual responds to the work situation with different degrees of effort. The bodily reactions to a high degree of effort are influenced by the concomitant degree of joy or distress in the situation. High effort with joy is labeled eustress while high effort with marked distress corresponds to a negative stress reaction.

The environmental counterpart of the effort–distress model is the demand–control model that has been used extensively. Accordingly this will be described in more detail. Karasek introduced the 'demand–control' model. It is a two-dimensional synthesis of the demand ('stress psychological') and the 'lack of control' (sociological) research traditions (Karasek and Theorell, 1990; Karasek, 1979). Lack of control has two components: 'Skill utilization' is related to the employee's control over the use and development of his/her skills, whereas 'authority over decisions' is related to the employee's control over decision-making relevant to his/her work tasks. The two factors are mostly added to one another to constitute 'decision latitude.'

The other dimension in the original demand–control model, psychological demands, includes both quantitative (how much work per time unit) and qualitative demands. Qualitative demands can be subdivided for instance into cognitive and emotional demands and demands to control one's emotions as in some kinds of health care work (Pejtersen et al., 2010). It has been claimed that different kinds of demands, for instance the ones related to intensity and to the number of working hours (extensiveness) should be treated separately for different groups of employees (Kristensen et al., 2004).

The high demand–low decision latitude combination, *job strain*, is regarded as the most dangerous in the development of illness. According to the theory, this kind of situation, if prolonged and repeated for a long time, increases sympatho-adrenal arousal and at the same time decreases anabolism, the body's ability to restore and repair tissues (Karasek and Theorell, 1990).

The combination of high psychological demands and high decision latitude is defined as the active situation. In this situation, the worker should be given more resources to cope with high psychological demands so that he/she can make relevant decisions, such as planning working hours according to his/her own biological rhythm. In addition he/she gets good possibilities to improve coping strategies – facilitating feelings of mastery and control in unforeseen situations. This situation corresponds to psychological growth.

The low demand–high decision latitude situation is the relaxed and theoretically ideal one, whereas the low demand–low decision latitude situation, which is labeled passive, may

be associated with risk of loss of skills and, to some extent, psychological capacity.

It soon became evident that a third component, social support, was needed in the demand–control model. This dimension had already been introduced previously in job stress research (House, 1981). Johnson has discussed this component extensively. He has pointed out that collective support may be difficult to separate theoretically from collective control. Workers who are exposed to adverse working conditions may join forces and increase their control over their working conditions. The worst hypothesized situation is 'iso-strain' – job strain and lack of social support (Johnson et al., 1989).

There is a striking difference between the effort–distress model and the demand–control model. Whereas the former is designed to explain differences in individual response to stressors, the latter is designed to assess the environmental conditions, – the stressors. There is of course a relationship between the models since eustress reactions are likely be more common in the 'active job' situation and negative stress reactions more common in the 'job strain' situation.

Interaction Between Individual and Environment

One of the most influential models has been that of the Michigan school, the PE fit model (Katz and Kahn, 1966). This theory postulates that adverse reactions at work arise when the PE fit is poor. In this model the interaction between a person's characteristics and the environment is the central theme. If the characteristics of the job do not fit the characteristics of the person there is a high likelihood that negative stress reactions may arise. There is considerable empirical support for this hypothesis (Kahn, 1981). Another important theme is the expectation of the person – those who have very positive expectations may be more disappointed than those who have negative expectations, if the conditions do not fit. The Michigan school also added social support at work as a central theme (House, 1981).

According to Siegrist (1996), a crucial job factor for health consequences is the degree to which the workers are rewarded for their efforts. When a high degree of effort does not meet a high degree of reward, emotional tensions arise and risk of illness increases. The 'effort–reward imbalance' model is described in another chapter by Siegrist in this book. It is a sociological theory that includes individual aspects. The effort component includes environmental (extrinsic effort, which is close to 'psychological demands' in the demand–control model) as well as individual aspects (intrinsic effort, overcommitment). A high degree of overcommitment could be the result of previous job experiences as well as of other experiences in the person's life. The reward component includes three different aspects of reward, namely monetary reward, promotion possibilities, and self-esteem. The construction of the questions specifically addresses whether the individual sees, for instance, a specific kind of extrinsic effort as a problem or not.

A more recent theoretical model related to the previous ones is the 'demand–resource' model (Demerouti et al., 2001). It is similar to the demand–control model, but it incorporates both individual and environmental resources. Whereas the demand–control model tries to focus on the organizational aspects of work, the demand–resource model has a mixed focus.

'Organizational justice' is another basic concept that has been used in job stress research. This concept builds upon the idea that job sites must have a system/organization for resolving conflicts and that this is important for employee health. It has also proved to be useful in illness prediction (Kivimäki et al., 2006).

Several multidimensional standardized questionnaires for the measurement of stressors and stress reactions at work have been published. The most extensively used one is the Occupational Stress Indicator (OSI), (Cooper and Payne, 1978; Cooper et al., 1988) that is based partly on the PE fit model and incorporates all of the dimensions in psychosocial work conditions.

During later years, considerable efforts have been made to explore the relationship between theoretical job stress models and 'hard endpoints' for health development. Previously scientific literature was criticized because most of the relationships had been observed in studies using self-reports both in descriptions of the stressors and the health outcomes (Kasl, 1982). There may be a risk in such studies that a pattern of complaining may affect both explaining variables and health outcomes. Therefore, studies have included prospective designs as well as objective outcomes (such as myocardial infarction or cardiac death) and objective recordings of stressors at work (through population means for each occupation regarding decision latitude, for instance; or by means of expert ratings of the crucial stressors). The demand–control model has been more extensively studied than the other models from this point of view.

Job Stress Models and Disease

The significance of the demand–control–support model to cardiovascular disease, in particular high blood pressure and myocardial infarction (Schnall et al, 1990; Theorell and Karasek, 1996; Melamed et al., 1998), has been tested in many epidemiological case-control as well as prospective studies. There is considerable support for the hypothesis that the combination of high demands and lack of control is associated with increased risk of developing myocardial infarction before retirement age. A recently published European study of a pooled cohort of almost 200 000 working men and women, showed a significant association between exposure to the combination of high psychological demands (above median for the demand scale) and low decision latitude (below median), and increased risk of developing a myocardial infarction during follow-up (Kivimäki et al., 2012). There were similar findings for men and women and they were robust when adjusted for age, other risk factors, and publication bias. The combination of high demands and low decision latitude was a better predictor than either demands or decision latitude separately. This study has been criticized because of the relatively weak exposure assessment with few questions assessing demand and decision latitude respectively. In addition, there was only one assessment of job strain before the follow-up started. It has been shown

that predictions gain precision if the exposure to job stress is assessed several times during the follow-up period, since participants experience changing work situations. It is therefore likely that the reported job strain-related myocardial infarction risk in the European pooled study (1.2 or 1.3) is lower than the true risk. In the early studies of demand and decision latitude in relation to myocardial infarction risk, the decision latitude was more important than the demand dimension but during recent years the opposite has been found to be true, possibly reflecting a changing working life (Eller et al., 2009). Loss of decision latitude has also been shown to be associated with increased risk of developing a first myocardial infarction in the near future, even after adjustment for other risk factors (Theorell et al., 1998). The support dimension has been less extensively studied than demand and control, but 'iso-strain,' – the combination of poor workplace support and job strain – has been shown to be associated with an increased development of the metabolic syndrome, which is a biological long-term consequence of adverse psychosocial stress and also a condition which increases the risk of developing cardiovascular disease (Chandola et al., 2010).

High blood pressure monitored during activities at work has shown a convincing relationship with job strain (Schnall et al., 1990; Laflamme et al., 1998; Riese et al., 2004). Serum lipids and smoking patterns have not shown consistent relationships with job strain (Theorell et al., 1998). Accelerated blood coagulation and activation of proinflammatory cytokines may be mechanisms that operate in the relationship between job strain and myocardial infarction risk, since studies have shown that high plasma fibrinogen (Tsutsumi et al., 1999; Brunner et al., 1996) and interleukin-6 (Theorell et al., 2000) are associated with low decision latitude and/or job strain.

Variations over time in job strain have been shown to be associated with changes in endocrine parameters and immune system function of relevance to stress theory. For instance, in one study of men, plasma testosterone (which is important to anabolism) decreased and immunoglobulin G increased (indicating increased immune system activity) when job strain increased and vice versa (Theorell et al., 1990a,b). In another study plasma testosterone increased when the total working life situation improved (Grossi et al., 1999).

Studies of the effort–reward model in relation to coronary heart disease (CHD) and its risk factors have also shown convincing relationships. A review by Kivimaki et al. (2006) showed that in men the CHD risk associated with effort–reward imbalance may even be more pronounced than the risk observed for job strain. High blood pressure and atherogenic lipids are associated with effort–reward imbalance. The patterns of association are different for men and women (Peter et al., 1998; Siegrist, 1996).

The PE fit model and related models have been used in studies of cardiovascular risk factors and positive findings have been reported (Cooper and Payne, 1978).

Musculoskeletal disorders such as low back pain and neck–shoulder pain have also been studied in relation to the demand–control model. The findings have been mixed. The relationships depend on the group and the kind of disorder studied. In some studies, social support at work is crucial whereas in others psychological demands or decision latitude may be important. When the associations between musculoskeletal disorder and psychosocial work environment are adjusted for physical load, the associations are often weakened. Among female workers, physical load and adverse psychosocial conditions are frequently correlated (Josephson et al., 1999). Vingård et al. (2000) showed that the prediction of the risk of developing an acute episode of low back pain is improved by combining psychosocial and physical working conditions. Similar findings have been made for neck–shoulder pain episodes (Wigaeus Tornqvist et al., 2001)

Integration of Effort–Reward Imbalance and Demand–Control

There is evidence (Bosma et al., 1998) that the decision latitude component of the demand–control model and the effort–reward imbalance model are contributing independently of one another to the prediction of episodes of CHD. Peter et al. (2002) found that a combination of the effort–reward and demand–control models provided better prediction of myocardial infarction risk than either one separately and also that the patterns were different for men and women. These findings confirm that the models are related to different psychosocial mechanisms linking psychosocial working conditions to health outcome. The models have psychological demands (extrinsic effort) in common but control (decision latitude) and reward are clearly different. A logical step would be to combine the models. Even when resources (control and support) are optimal for the development of good coping strategies in a highly demanding situation, the employees will need reward for high effort, and hence balance between the components is needed.

Most of the relationships that have been observed in this field would be without significance in society if it were not possible to prove that it is possible to improve health by means of changes in working conditions. Accordingly, the literature on job interventions and their possible effects on health is of considerable importance.

Other Job Stress Related Outcomes

Of particular importance to the link between job stress and cardiovascular disease is the development of atherosclerosis. During recent years it has become increasingly common to measure wall thickness in the carotid arteries – intima media thickness (IMT) – since this reveals early as well as late signs of atherosclerosis. In-depth studies of the early stages of atherosclerosis have shown that psychosocial stress is of significance. Sympathetic arousal increases the likelihood of soft plaques in the arterial wall through a complicated physiological process involving proinflammatory cytokines. Effective activation of the parasympathetic system and rapid slowing of the sympathetic system increases the likelihood that these reactions will be counteracted and the soft plaque will disappear without developing into more severe forms of atherosclerosis (De Couck et al., 2012). In consequence, there are studies which have shown that both the demand–control and

effort–reward models are useful in predictions of progression of IMT over time (Eller, 2012).

Another important step in the efforts to explore easily applicable biological stress markers that can be used in practice in the workplace has been the introduction of salivary cortisol measures. There has been great hope that salivary cortisol which mirrors the concentration of free cortisol in plasma would be a very useful indicator. It has been shown that the rise of the salivary cortisol from awakening to half an hour later, is a useful measure of the arousal associated with the day. The findings so far have been mixed (Kristenson et al., 2012) with regard to the usefulness of salivary cortisol variation in general as an index of stress states, with some significant findings for both models in some studies but null findings in several others (Karlson et al., 2012). Paid work is impossible if there is severe HPA regulation disturbance (see above). Most of the work stressors are of a mild nature and large samples are therefore needed for the study of these associations. The interpretations are complicated by the fact that the feeling of being stressed is dampened by a strong cortisol response (Het et al., 2012) and hence simple correlations between self-reported exposure intensity at work and cortisol level cannot be expected. Stressor peaks at work occur unexpectedly and when they occur, the subjects may not report feeling stressed (*because of* the cortisol peak). In a careful study – with a large number of observations – of the daily stressors for neonatal pediatricians and nurses in critical care, objectively assessed events gave rise to cortisol peaks; but almost three fourths of these peaks were not described as stressful by the subjects themselves (Fischer et al., 2000).

Another outcome that is relevant in linking job stress to illness is heart rate variability (HRV) that is recorded by means of continuous ECG recordings. As long as the subject does not have a large number of cardiac arrhythmias, a high variability in heart rate is an index of good health. Subjects with exhaustion and depression have low total HRV. There are also different components in HRV; 'high frequency' variations are reportedly related to the activity in the parasympathetic system whereas the ratio between 'low frequency' and 'high frequency' variations have been assumed to reflect sympatho-adrenal activity. There are many technical problems in interpreting the recordings and it also makes a difference whether recordings are made on a total day–night variability basis or whether short recordings are made during defined external conditions. Both the demand–control and the effort–reward models have been related to HRV. Thus job strain as well as lack of control (decision latitude) and effort–reward imbalance have been shown in several studies to be related to low total HRV, reduced high frequency power, and high ratio between low and high frequency power (Eller, 2012).

A great emphasis in the present survey has been on cardiovascular disease and related outcomes. The rationale behind this is that cardiovascular disease is an important health outcome that is partly determined by stress-related factors. However, many reports of relevance to job stress deal with emotional outcomes such as depression, depressive feelings, anxiety disorders, and anxious feelings as well as emotional exhaustion and burnout. A recent summary of prospective studies by Bonde (2011) concluded that perception of adverse psychosocial factors (predominantly the demand–control and effort–reward models or their components but also job insecurity and organizational justice) is related to an elevated risk of subsequent depressive symptoms or major depressive episodes.

Environmental and Individual Psychosocial Interventions at Work

Very few studies have actually documented the health consequences of psychosocial job interventions. One early study of cardiovascular risk factors (Orth-Gomér et al., 1994) showed that a program aiming at improved decision latitude and social support for the employees was followed by improved ratio between harmful and protective cholesterol (that is associated with reduced CHD risk) in the experimental but not in the comparison group. The findings could be interpreted to mean that job redesign aiming at improved social relationships and decision latitude could lead to decreased cardiovascular risk. Recently Brisson et al. (2006) have performed controlled evaluations of work organization intervention for health care workers. The intervention program was building upon the demand–control and effort–reward models. It was instituted in close collaboration with the participating worksites and adapted to the specific conditions of each site. Significant effects were reported on mental health outcomes. This group has later developed their intervention program and in new reports significant intervention effects in the form of reduced blood pressure have been reported (Trudel et al., 2011).

Experiences in all EU countries have been summarized (Kompier and Cooper, 1999). Evaluations of systematic efforts to improve working conditions by means of increased decision latitude, support, organizational justice, and reward in order to improve health have typically been more common in the Northern countries.

Recent evaluation studies of the effects of programs for improving managers' ability to decrease employee stress have been promising (Theorell et al., 2001; Romanowska et al., 2011).

Ongoing Trends

In an increasingly unstable labor market in the future, employment security will become less common and global competition will increase (Aronsson and Göransson, 1999; Johnson, 2008). In most European countries there has been a clear rise in work intensity since the beginning of the 1990s. There have been pronounced changes in the organization of the public sector. In the Nordic countries, for instance, there has also been a decrease in perceived decision authority since the late 1990s particularly among women working in health care and education. Problems with decision authority have arisen during a period when management philosophy has changed in the direction of more financial emphasis. Psychological demands will continue to rise, both because there is more cognitive demand (memorizing numbers, handling computers, etc.) and more emotional demands due to increased customer

demands. Numbers of collaborative partners are rising because of the increasing specialization of work, and thus there will be an increasing likelihood of complicated emotional communication for everybody.

Studies in several countries have already shown that workers in temporary employment have a bad position in decision processes. There are indications from several countries that differences in health between favored and less favored workers will increase. The importance of effort–reward balance and organizational justice increases in efforts to decrease job stress.

The basis for social support will change gradually since workers on all levels will rotate more frequently between worksites in different projects than previously. Employers will have a special responsibility for the organization of social support in worksites.

Abstract

This article traces the legal regulation of the health and safety of workers and others at work, from the early nineteenth century to the widespread reforms in occupational health and safety (OHS) regulation since the 1970s. The emphasis is on Europe, North America, and Australia. The article examines four themes of particular importance in the development of OHS regulatory regimes, wherever found. These are the different styles of OHS standard setting, the variable models of enforcement by state-sponsored inspectorates, and the legal institutions that promote worker participation in OHS. The article concludes with a discussion on the OHS regulation in developing countries.

This article outlines developments in the legal regulation of the health and safety of workers and others at work. It does not purport to offer a comprehensive survey of international occupational health and safety (OHS) practice and theoretical perspectives. Instead, it traces historically the main developments in the field of OHS regulation, with an emphasis on Europe, North America, and Australia. Within this framework, and with a special focus on the movement from command and control to self-regulatory models (or, more accurately, models of enforced self-regulation), the article examines four themes of particular importance in the development of OHS regulatory regimes, wherever found. These are the distinguishable features of OHS standard setting, requirements that duty holders seek expert assistance to improve compliance with OHS standards, the variable models of enforcement, and the relationship between OHS and industrial relations. The article concludes with a discussion on the difficulties of regulating OHS in developing countries.

The Emergence of the Traditional Approach to OHS Regulation

OHS regulation is generally traced back to the early nineteenth-century Factory Acts in the United Kingdom. The earliest enactment was the Health and Morals of Apprentices Act of 1802, essentially an extension of Elizabethan Poor Law. It regulated the working hours and conditions of apprentice pauper children in the water-based rural cotton factories of Northern England. The enforcement provisions relied on informers and visitors appointed by the magistracy from the clergy and justices of the peace, but were generally regarded as completely ineffective (Thomas, 1948; pp. 11–12), largely because of the limited powers given to visitors, magistrates' lack of interest in the factory legislation, and the fact that magistrates were too closely linked to mill owners to enforce the law (Gunningham, 1984; p. 38).

The ineffectiveness of this early factory legislation led to the enactment of the Factory Regulation Act of 1833, which regulated the employment of children in a wide range of textile trades. While the enactment of this law was partly a response to working-class pressure, and partly a response to agitation by middle- and upper-class philanthropists for shorter working hours for children and young people, it was undoubtedly also a result of calls for effective uniform regulation by larger urban manufacturers who had voluntarily introduced shorter working hours and who feared unscrupulous competition from smaller and rural-based manufacturers (Carson, 1974; Marvel, 1977).

The 1833 Act was the first to be enforced by an independent, salaried, factory inspectorate vested with broad powers, including the right of entry to factories and mills; the right to make rules, regulations, and orders; and the power to initiate and hear court proceedings to enforce the Act. Over time, however, these broad powers of inspectors were reduced to inspecting and taking enforcement action – a more 'legalist' regulatory form. This development was initiated by the inspectors themselves, to overcome allegations of class bias by presenting decision-making as a passive, neutral, nondiscretionary, and technical process of implementation of the rules set out in the Act (Field, 1990).

After initially making frequent use of prosecution to enforce the Act, the inspectors soon relied mainly on advice and persuasion to induce compliance, with prosecution a 'last resort.' Bartrip and Fenn (1983) suggest that, in doing so, inspectors were taking a cost-effective approach to enforcement. Prosecutions were time-consuming and costly; over time the ratio of inspectors to factory premises worsened significantly so that each inspector had an increasing number of factories to inspect; inspectors were ambivalent about the degree to which regulatory offenses committed by businesses creating wealth and employment were morally reprehensible; and inspectors were deterred by hostile attitudes of magistrates toward the provisions of the Act.

Taking a broader political economy approach, Carson (1979, 1980) has posed an alternative explanation of the origins of this approach to enforcement. He argues that by 1833 a number of large, urban manufacturers, for various reasons, supported the provisions of the 1833 Act, including strong enforcement by the inspectorate. The inspectors, however, found that their assumption that offenses against the Act were being committed by only a few employers was ill-founded, and that contraventions were widespread, and intrinsic to the prevailing production system (Carson, 1979). The heavy use of prosecution would have entailed "collective

criminalization" of employers "of considerable status, social respectability and … growing political influence" (Carson, 1979; p. 48). As a consequence, the early inspectors developed an approach to enforcement that relied principally on advice and persuasion, and resorted to formal prosecution only in the worst cases and where there was evidence of willful employer disobedience or obstinacy. Although officially criminal offenses, contraventions of the Factory Act were accepted as customary and those responsible were rarely subjected to criminal prosecution (the 'conventionalization' of factory crime; Carson, 1979). This 'ambiguity' of factory crime (Carson, 1980), although historically contingent, has proved to be deeply entrenched ideologically in most of the world's OHS regulatory systems.

The Factories Amendment Act of 1844 extended the coverage of the legislation to the working hours of women and included the first machinery safety provisions. In compliance with inspectors' wishes, it also deleted all references to willfulness in many of the employers' offenses (Carson, 1979; pp. 53–54). The 1833 and 1844 Acts marked the beginning of the traditional approach to the regulation of health and safety at work, in which the government set down highly detailed and technical requirements in strict liability 'specification' standards, and provided for the enforcement of these standards by a state inspectorate that relied principally on informal enforcement responses. This regulatory model was reproduced in other industries in Britain and was transported to the British colonies, including Australia, Canada, India, and New Zealand.

While these developments in the United Kingdom strongly influenced the OHS regulatory provisions of the rest of Europe (see Baldwin and Daintith, 1992), the regulatory approach in each European state was also shaped by national political considerations and the regulatory practices in the more powerful industrializing continental European countries, particularly Germany and France (Walters et al., 2011; p. 23). The German 'dual system' developed in the late nineteenth century. It comprised legislative standards enforced by a state inspectorate and complementary regulation by statutory mutual insurance companies (Schaapman, 2002). The legislative standards were not to be found in a specific OHS statute or code, but rather in paragraph 120(a) of the general Industrial Code (*Reichsgewerbeordnung*) for industry and paragraph 62 of the Business Code for commerce (Walters et al., 2011; p. 24). The first German Labor Inspectorate (established in 1853) was an optional service, and only in 1878 was an obligatory government inspectorate established to monitor and enforce the provisions of the Codes. In tandem with this state regulation was a second track of regulation and enforcement, initially enacted by the Industrial Accident Insurance Act of 1884, which created accident insurance funds (*Unfallversicherungsträger*) of which industrial employers' liability insurance funds (the *Berufsgenossenschaften*) were and are the most important. These bodies were responsible not only for compensation functions, but also for the prevention of illness and injury at work by making regulations to prevent injury and disease and enforcing those regulations through technical inspection services (Schaapman, 2002).

Subsequent development of the OHS regulatory provisions in Europe (and in the British colonies) in the first half of the twentieth century was piecemeal, in that detailed and technical standards ('prescriptive' or 'specification' standards) were introduced from time to time to address particular hazards, processes, or premises. One significant development during this period happened in Sweden, where in 1938 the employers and trade unions negotiated the Saltsjobaden Agreement to resolve a long period of industrial conflict. This agreement was a foundation stone in the development of Swedish corporatism, and in the development of participatory approaches to OHS at national, sectoral, and workplace levels (Walters et al., 2011; pp. 26, 122–123). Another important development was the introduction of occupational health services in some European countries, beginning with Norway in the late nineteenth century, and legislation to require firms to make use of occupational health services in addressing OHS issues. For example, France in 1946 passed legislation introducing occupational health services.

In the United States, similar models of OHS regulation were established at the state level from the late 1860s until the end of the nineteenth century. The state level statutes contained detailed, technical standards that focused on certain kinds of premises (such as factories), processes, or activities. The federal government relied on state regulation until 1970, when the Occupational Safety and Health Act (OSH Act) was enacted (Ashford, 1976; Noble, 1986).

Criticisms of the Traditional Command and Control Approach

The weaknesses of this traditional approach are well known (see Robens, 1972) and are widely regarded as having international relevance, because most OHS regulatory systems relied on detailed, technical prescriptive or specification standards enforced by state inspectorates. This traditional approach frequently resulted in a mass of detailed and technical rules, often difficult to understand and difficult to keep up to date. Standards were developed ad hoc to resolve problems as they arose, and concentrated mainly on factory-based physical hazards, resulting in uneven coverage across workplaces. Specification standards did not encourage or even enable employers to be innovative and to look for cheaper or more cost-efficient solutions. They also ignored the now well-accepted view that many hazards do not arise from the static features of the workplace, but from the way work is organized.

Critics have also pointed to the inadequacy of state approaches to enforcement, and to the ideological role of traditional factory legislation in encouraging dependency on state measures and in separating OHS from the conflictual terrain of industrial relations. This separation impedes the involvement of workers and their representatives in developing standards and measures for improving health and safety at the workplace. As noted previously, one exception to this trend has been some of the Scandinavian countries, most notably Sweden, which, from early in the twentieth century, has provided for trade union involvement in OHS (Navarro, 1983).

Since 1970, there have been major developments in the regulation of OHS. The general trend has been away from traditional 'command and control' models toward a more 'self-regulatory' system in which duty holders are given more

flexibility and choice of methods to achieve OHS standards. Under this approach there is greater opportunity for worker involvement in OHS, and approaches to state inspection focus as much on systems of work as on workplace hardware. In many countries, inspectors have been given a wider range of enforcement powers, including administrative sanctions intended to remedy hazards rather than punish offending duty holders.

The Modern Approach to OHS Regulation

Standard Setting

Since the mid-1970s, the trend in Europe, North America, and Australasia, and many countries in Asia, Africa, and South America, has been to replace or supplement specification standards with a combination of general duties, performance standards, process requirements, and documentation requirements. The trend has been most marked in Europe, Canada, and Australia, where the general duties increasingly have become process standards, and the subordinate legislation underpinning the general duties – regulations and guidance material – has increasingly adopted process, performance, and documentation standards.

The 'general duty' provisions require the duty holder (usually the employer, but in some countries including the self-employed, occupiers of workplaces, and manufacturers, suppliers, and designers of plant, substances and structures) to exercise reasonable care in the provision and maintenance of systems of work so as to ensure that workers are not exposed to health and safety risks. For example, the U.S. OSH Act of 1970 section 5 specifies that in all cases not covered by specific standards promulgated under the Act, the employer has a general duty to "furnish to each of his employees, employment and a place of employment which are free from recognized hazards that are causing or are likely to cause death or serious physical harm to his employees."

As this example shows, the post-1970s trend has been to base the general duties on the 'employment paradigm' – that is, the relationship between employers and employees. The dominance of this paradigm has been challenged since the 1980s by changes in work arrangements and, consequently, work relationships around the world, with employers increasingly outsourcing work to contractors and subcontractors, contracting with agencies in order to lease labor, or establishing franchise arrangements (see Walters et al., 2011; pp. 40–42). Research has documented the negative effect of these various work arrangements on the health, safety, and well-being of workers engaged in those arrangements, as measured by injury rates, disease, hazardous substance exposures, mental health, and work health and safety knowledge and compliance (see, for example, Quinlan et al., 2001a; b). This has caused some countries to move away from placing duties on 'employers' in relation to 'employees.' For example, in 2009, the Australian Commonwealth, state, and territory governments endorsed a Model Work Health and Safety Bill in which the primary duty holder is not the employer, but rather "a person conducting a business or undertaking," and this duty is owed to all types of workers 'engaged,' 'caused to be engaged,' 'influenced,' or 'directed' by the person conducting a business or undertaking. Further, a 'worker' is defined very broadly to include any person who carries out "*work in any capacity for* a person conducting a business or undertaking," and includes, for example, work as a contractor or subcontractor, work under a labor leasing agreement, or work as a volunteer.

The general duty provisions tend to be supplemented by a range of standards set out in subordinate legislation, which, increasingly in many countries, has moved away from specification standards to general duty approaches, and performance, process, and documentation standards.

Instead of telling duty holders exactly how they are to achieve compliance, performance standards define the duty holder's duty in terms of goals they must achieve, or problems they must solve, and leave it to the initiative of the duty holder to work out the best and most efficient method for achieving the specified standard.

Process requirements (sometimes known as 'management standards') prescribe a process, or series of steps, that must be followed by a duty holder in managing specific hazards, or OHS generally. They are often used when the regulator has difficulty specifying a goal or outcome, but has confidence that the risk of illness or injury will be significantly reduced if the specified process is followed. Typically, these standards require employers "to take an active, comprehensive, programmatic and enduring responsibility for OHS quality, through a systematic managerial process to detect, abate and prevent workplace hazards" (Frick et al., 2000; p. 1). For example, as a result of the EC Framework Directive of 1989, On the Introduction of Measures to Encourage Improvements in the Safety and Health of Workers at Work, all EC member states are required to introduce risk assessment processes into their OHS statutes. Consequently, the general duty provisions in most EC countries are couched as risk management standards (see Walters et al., 2011; pp. 32–40).

Process-based standards have spawned greater reliance on documentation requirements. Increasingly, OHS statutes are requiring duty holders to document measures they have taken to comply with process-based standards, performance standards, and general duty standards. An example is the requirement for health and safety plans and files in the 1992 EC Directive to Implement Minimum Health and Safety Requirements at Temporary or Mobile Construction Sites.

A current debate in OHS standard setting is whether OHS regulators can take measures to require employers and other duty holders to go beyond compliance with minimum standards, and to implement comprehensive OHS management systems that involve continuous improvement and a systems-approach to OHS management (see Frick et al., 2000; Gunningham and Johnstone, 1999). The debate is most advanced in provisions for the management of major hazardous facilities, which have largely been enacted in reaction to major disasters, and in the mining industry. Many jurisdictions now require facility operators to submit a 'safety case' for each of its installations, demonstrating that they have evaluated risks and set up a system of management and control to deal with the identified risks (Cullen, 1990; Gunningham, 2007; Kaasen, 1991; see the International Labour Organization's 1993 Convention on the Prevention of Major Industrial Accidents, and EU Directives 82/501/EEC and 96/82/EEC on the control of major hazard facilities).

The duties discussed thus far are duties imposed on the enterprise – usually a corporate entity, but occasionally a sole proprietor, partnership, voluntary association, or similar arrangement. A corporation is a fictional legal entity, and can operate only through its human directors, managers, and workers. Most contemporary OHS statutes impose duties of care on employees (and occasionally on other kinds of workers, who may not technically be 'employees') to ensure their own health and safety and the health and safety of others. Senior management leadership in OHS is critical to positive health and safety outcomes. Accordingly, some countries have also imposed duties on high-level corporate officers (who may also be employees and thus subject to the employee's duty as well).

For example, section 37 of the Health and Safety at Work etc Act of 1974 (UK) provides that where a body corporate's offense under the Act is proved to have been committed with the consent or connivance of, or to have been attributable to any neglect on the part of, any director, manager, secretary, or other officer of the body corporate, that officer is also guilty of the offense. This form of accessorial liability can also be found in Hong Kong, New Zealand, and the Australian state of Western Australia. Other statutes, such as those in Singapore or Malaysia, the Canadian province of British Columbia, and the Australian states of Victoria and South Australia, impute liability to an officer for a corporate OHS offense, and might give the officer a defense of due diligence, or only impose liability if the officer fails to exercise reasonable care. Some countries – for example, Germany, the Canadian province of Ontario, and the Australian jurisdictions adopting the Model Work Health and Safety Bill – are now imposing 'positive' duties on corporate officers to take reasonable care or to exercise due diligence. Because these latter duties are positive duties to ensure that the corporation complies with its OHS duties, inspectorates can take measures such as administrative sanctions if the officer fails to exercise due diligence or take reasonable care to ensure corporate compliance. In some countries, duties are imposed on individuals within the corporation rather than on the corporation itself. For example, in France duties are imposed on the Head of the Establishment (a director or a senior manager) and in Sweden, even though the duties are placed on the employer, the responsibility is borne primarily by the most senior manager. (For further discussion of these approaches, see Bergman et al., (2007)). In other countries – for example, the United States and the Netherlands – no provision is made for officer liability.

Provisions Requiring Duty Holders to Seek Expert Assistance in OHS

The modern OHS standards, with their reliance on performance and process (OHS management) standards, are demanding and often complex. While there is plenty of evidence to show that the promotion of systematic OHS management in OHS regulation is a positive development, improving management awareness of and involvement in OHS management (for a summary, see Quinlan et al., 2010; p. 358), it is also clear that duty holders often find it difficult to introduce effective measures to identify, assess, and eliminate or minimize OHS risks (see Walters et al., 2011; pp. 8–9). This is especially the case with small businesses (Hasle et al., 2009). Occupational health services can play an important role in supporting employers and improving their understanding of OHS matters. In the 1970s, Denmark, Sweden, and Norway, and in 1996 the Netherlands, legislated to require firms to engage occupational health services. Germany in 1974 required all firms to appoint occupational physicians and occupational safety specialists. The EC Framework Directive (1989) requires employers to enlist "competent services or persons" to assist in the implementation of the OHS duties in the Directive and "to organize protective and preventive measures." For example, consistent with provisions in other continental European nations, the Swedish Work Environment Act requires employers to provide an occupational health service. Most large companies have their own occupational health services, while joint occupational health service centers provide services to small- and medium-sized organizations. This continental tradition is not followed elsewhere, although UK regulations and some Australian and Canadian statutes require the appointment of 'competent persons' (and until 2012 Queensland required the appointment of workplace health and safety officers in large firms) to assist employers in implementing their OHS obligations.

Worker Participation

The nineteenth-century model of OHS regulation typically did not require worker involvement in OHS. There are, however, good reasons for involving workers in OHS. From an ethical perspective, workers have a direct interest in OHS because they run the major risks of injury if the law fails to protect them. Moreover, workers often know more about the hazards associated with their workplace than anyone else, because they regularly work with them. Where process standards require hazards at work to be identified and evaluated, workers' experience and knowledge is crucially important in successfully completing both of these tasks. Further, research from many countries demonstrates the positive benefits of worker participation in work health and safety, including a relationship between workplace structures enabling worker representation (union presence, joint safety committees, or worker/union safety representatives) and both objective indicators of OHS performance (such as reduced injury rates or hazard exposures) and better OHS management arrangements (see Walters and Nichols, 2007; Chapter 2).

European, Canadian, and Australian OHS statutes have made some statutory provision for OHS committees, and for worker health and safety representatives. Representatives generally have the right to inspect workplaces, to be consulted over OHS issues, and to be provided with OHS information. Some European, Australian, and Canadian statutes go further, and give elected health and safety representatives the right to require compliance with OHS regulatory provisions and to direct that dangerous work ceases. The EC Framework Directive requires employers to involve workers and their representatives in the implementation of the various duties set out in the directive. The U.S. OSH Act to date has made no provision for worker participation in OHS, although the Occupational Safety and Health Administration's (OSHA's) recent proposed safety and health program rule requires worker involvement in the development of a safety and health program.

In contrast, in Scandinavia, the worker participation elements of the OHS regulatory system derive from the general industrial relations system, and do not depend on the OHS statutory framework. For example, the Swedish Work Environment Act of 1977 enshrines the concept that worker control is a critical aspect of a healthy working environment, and provides health and safety representatives with extensive powers, including the right to halt dangerous processes and to participate in the planning of new work premises and processes. Industrial and local agreements regulate much of the administration of OHS. In Sweden, Spain, Italy, and Norway, the construction industry makes provision for coverage of small workplaces by enabling unions to nominate regional safety representatives for small workplaces (normally under 50 workers) to support the OHS initiatives by employers (see further Frick, 2009).

State Enforcement of OHS Obligations

The modern OHS inspectorates can call on a range of enforcement powers, usually culminating in prosecution. In most countries, inspectorates have a broad discretion to determine enforcement action, including negotiating compliance using informal processes such as education, advice, and persuasion. Since the 1970s, inspectorates in most countries have been given administrative sanctions such as improvement and prohibition notices and on-the-spot fines (usually imposing small fixed fines). In some countries inspectorates have the power to impose significant variable administrative penalties. For example, German Insurance Association inspectors can impose fines determined by reference to the amount of money that the firm has saved through noncompliance (Fooks et al., 2007; p. 43). In British Columbia, the basic penalty is assessed using multipliers relating to the size of the employer's assessable payroll, and can be adjusted up to 30 percent by reference to a range of aggravating and mitigating factors, and up to 24-fold if it is a repeat of a contravention committed within the previous three years; it can be even higher if willful or reckless contraventions result in death (see Fooks et al., 2007; pp. 43–44). In Australia since 2003 some OHS regulators have had the power to accept 'enforceable undertakings' in lieu of launching a prosecution for a contravention of the OHS statute. Enforceable undertakings are promises enforceable in court, and are usually offered by an individual or firm who has allegedly breached the law, and accepted by a regulator. If contravened, the undertaking is enforceable in court, often with additional penalties for the contravention of the undertaking (see Johnstone and King, 2008).

In the United States, enforcement is less discretionary, and principally involves administrative sanctions (citations imposing financial penalties and requiring the abatement of hazards) (see Kalestsky, 1997; Shapiro and Rabinowitz, 1997), with prosecution for a limited number of intention-based offenses. In other countries, the OHS inspectorates have been criticized for not adopting a sufficiently strong approach to enforcement, and for relying too heavily on advisory and persuasive approaches. Some commentators argue for a more vigorous approach to enforcement using the self-regulatory principles of the enforcement pyramid (a hierarchy of escalating sanctions) promoted by many regulatory theorists (see Ayres and Braithwaite, 1992; Chapter 2; Rees, 1988; see also Wright et al., 2004; p. vi). The challenge is to develop enforcement strategies that deter the worst offenders, while at the same time encourage and help most employers comply voluntarily. Such an approach to enforcement would require the availability of larger financial penalties and an array of new corporate sanctions (Gunningham and Johnstone, 1999; Chapter 4).

Inspection Approaches Aimed at Promoting OHS Management Systems

In some countries, OHS inspectorates have developed enforcement strategies that focus as much on OHS management as on workplace hardware. For example, in the United States, some OSHA inspection programs abbreviate inspections if employers can show that they have effective safety and health programs. Under the focused inspection program, piloted in the construction industry, if an OSHA inspector conducts an inspection and finds an effective safety program operating on site, then the remainder of the inspection will be limited to the top four hazards that kill workers in the construction industry. If these hazards are well controlled, the inspector concludes the inspection. If not, the inspector conducts a complete site inspection.

Such approaches to inspection are also increasingly being used in Europe and Scandinavia (see Walters et al., 2011). In Sweden, the Swedish Work Environment Authority inspectors routinely inspect 'Systematic Work Environment Management' (SWEM) when they visit workplaces – both by asking management about SWEM and by physical examination of OHS risks at the workplace (see Walters et al., 2011; Chapters 6 and 7).

Recent research suggests, however, that despite the regulatory shift in many countries to OHS management standards, and the increased focus of inspectors on inspecting systematic OHS management, "in most cases these changes have not resulted in clearly defined inspection strategies to achieve improved" OHS management, nor "have they given rise to sustained changes in regulatory inspection practice" (Walters et al., 2011; p. 308).

OHS Regulation in Developing Countries

The discussion so far has addressed the development of OHS regulation in developed countries. OHS and the regulation of OHS in African, South and Central American, and Asian and Pacific island countries face many obstacles not found in developed countries. In many developing countries these challenges include the rapid expansion of the informal economy, where economic activity is not recognized or protected by state authorities; the growth of new industries, some of which are difficult to regulate; and the outsourcing of production by the use of transnational supply chains enabling firms based in developed countries to exploit labor in developing countries from a distance (see Johnstone, 2012). At a broad level, OHS in developing countries is often competing with other priorities, for example, poverty alleviation, HIV/AIDS, and water and sanitation issues (Gutierrez, 2000). OHS regulatory measures can be undermined by inadequate levels

of education and deeply entrenched social and gender inequality, persistent poverty, threats to peace and security, and deregulation and reduced state intervention in the economy (World Health Organization, 2005; p. 20). Further, the contemporary approach to OHS regulation in developed countries demands significant resources from firms, unions, and regulators, resources that generally are not available to regulators, unions, and local small and medium-sized businesses in developing countries.

Many of these issues are a result of intensified globalization, and in particular the ability of capital to shift production to developing countries by direct investment in plant in developing countries, through supply chains or through purchasing contracts. The protection of workers' health is consequently a global issue, and needs global solutions built on cooperation between developed and developing countries (Johnstone, 2012). This requires consideration of matters such as the political, social, and economic dynamics leading to poor OHS in developing countries; how informal sectors might be effectively 'formalized' and properly regulated; how legally enforceable supply chain regulation in developed countries might be extended globally and greater cross jurisdictional cooperation be encouraged; and how the major international institutions, and international collaboration between developing and developed countries, can address the underlying factors leading to poor OHS in developing countries, and improve resources for OHS, and OHS regulation, in those countries (Johnstone, 2012).

Occupational Stress Management

Abstract

Work stress as measured by the work stress models of job strain, effort–reward imbalance, or injustice increases the risk for mental, psychosomatic, and cardiovascular disorders. On an individual level, interventions based on the principles of cognitive behavioral therapy are most effective and improve mental health outcomes immediately after the intervention. Little is known about long-term effects, and other outcomes. On an organizational level, interventions may effectively improve working conditions. However, results are heterogeneous as these interventions are highly sensitive to external disturbances, and require a systematic approach for sustainable implementation. The synergy between organizational- and individual-level interventions has not yet been fully used.

Introduction

Due to the changes within the working environment, especially in Europe and North America, some of the most hazardous work-related stressors nowadays are psychosocial stressors. A large body of scientific evidence based on cohort studies, experimental research, controlled randomized studies, and meta-analyses supports this hypothesis. Psychosocial work stressors have a significant impact on mental, psychosomatic, and cardiovascular health (Stansfeld and Candy, 2006; Kivimäki et al., 2007; Ndjaboué et al., 2012; Bambra et al., 2009). Musculoskeletal pain and cardiovascular disorders represent major causes for disabilities, absenteeism, and medical costs. Mental disorders, such as anxiety or depression, are increasing and account for a major burden of disease worldwide. Costs are high due to patients' impaired social functioning and sometimes poor integration into society, an above-average rate of unemployment and, more importantly for the working environment, a substantial reduction of productivity, an increase in absenteeism, or even permanent disability to work. The projection of the WHO Burden of Disease Project (Mathers and Loncar, 2006) implies a rising economic and social burden, which does not even sufficiently account for the burden on the social networks and families of affected patients. Health promotion and prevention of disease by improving work conditions and mitigating the impact of work stress on health must be one of the primary goals for health policy.

In the following article, we will briefly review the impact of work stress on health and outline the two major approaches to occupational stress management, the individual- and the organizational-level approach.

Occupational Stress Models

For the sake of clarity, some important terms related to occupational stress should be explained first.

In occupational contexts, *stress* can be defined as the psychological, physiological, or behavioral *response of a person* to a given work situation. Stress responses are determined by the quality and intensity of the working conditions, the duration of exposure, as well as on the enduring and momentary abilities and appraisals of the employee. Stress responses include not only physiological arousal like increased blood pressure and feelings such as to be challenged, but also anxiety, irritation, and rumination. Long-term consequences of stress on health and well-being mainly depend on the stress level and on the available internal and external resources to return to an equilibrium state. Stress mechanisms and their link to health are described in more detail elsewhere in this volume.

Although stress depends, to some extent, on individual conditions (e.g., Lazarus and Folkman, 1984), occupational stress models postulate that certain constellations of *external working conditions* (work tasks, work organization, social relationships at work, and environmental conditions) have a significant impact on health and well-being of the vast majority of employees. Generally, such occupational stress models distinguish between 'job demands' and 'job resources' considering the differential health-related impact of working conditions (e.g., Bakker and Demerouti, 2007).

Job demands, on the one hand, are all kinds of working conditions that require mental or physical energy. Within the job demands dimension, one can further distinguish between demands that constrain task accomplishment (i.e., *hindrance stressors* like interruptions or role conflicts) and demands that potentially provide the opportunity for personal development and growth (i.e., *challenge stressors* like task variety or complete tasks) (e.g., Podsakoff et al., 2007). This last-mentioned distinction is useful because challenge and hindrance stressors might be associated with health and well-being in a different way: Hindrance stressors might be a risk factor in any case, because they have to be compensated by additional efforts, and might be evaluated by employees as unnecessary or illegitimate (Semmer et al., 2010). Challenge stressors might only be a risk factor in case demands clearly fall below or exceed the capabilities of employees, but they are expected to contribute positively to health and well-being when there is a balanced relation to the capabilities of employees. *Job resources*, on the other hand, are regarded as working conditions that support people in accomplishing their work as well as safeguard

personal integrity and as such promote health and well-being (e.g., autonomy, social support, esteem).

Before describing basic intervention strategies, the most prominent occupational stress models are presented in the following section.

Job Demand-Control-Support Model

The Job Demand-Control (JDC) model established by Karasek (1979) is based on the idea that high job demands (e.g., high workload, time pressure) impair health particularly when employees possess only limited job control (e.g., narrow options to decide when and how to do the work). In contrast, work that includes high demands *and* high job control is expected to have a motivating function and to be conducive to learning. Accordingly, recent meta-analyses of epidemiological studies show that the combination of high job demands and low job control increased the risk of coronary heart disease (Kivimäki et al., 2012) and mental disorders (Stansfeld and Candy, 2006).

Beyond that, social support given through supervisors or colleagues is expected to have a direct stress-reducing and health-promoting effect and, above all, a buffering effect of job demands and job control on health (Johnson and Hall, 1988). Being short on experiencing social support comes with an increase in the risk of mental disorders (Stansfeld and Candy, 2006) and back pain (Hoogendoorn et al., 2000). Social issues should thus be considered when analyzing and designing work tasks (e.g., cooperation requirements), the work environment (e.g., common areas), and work organization (e.g., time buffers for mutual support).

Effort–Reward Imbalance Model

While the JDC model holds that individual control and decision-making opportunities are existential human needs and thus a prerequisite for health, the Effort–Reward Imbalance (ERI) model (Siegrist, 1996) is based on the idea that work can be further perceived as a social exchange process of individual efforts and received reward. High effort is fostered through high job demands (see above). Reward is particularly shown by money, esteem, career opportunities, and job security. An imbalance between high effort and low reward is expected to cause health impairments. There is good empirical evidence for this basic hypothesis of the ERI model, especially in regard to the association with coronary heart diseases (Kivimäki et al., 2006) and with mental disorders (Stansfeld and Candy, 2006).

Organizational Justice

Like the ERI model, organizational justice approaches are related to aspects of a fair distribution of rewards, but additionally encompassing a component of procedural and interpersonal of fairness (Greenberg, 1990). Procedural justice exists if employees are informed about important organizational matters and if decisions are made and implemented after participation of all parties. Relational justice particularly refers to the fair and respectful treatment of employees by their supervisors. Empirically, organizational justice is shown to be related to various health outcomes like cardiovascular disease and cardiovascular mortality as well as psychiatric disorders (Elovainio et al., 2010).

The Job Characteristic Model

The Job Characteristic model (Hackman and Oldham, 1980) specifically describes working conditions that contribute to intrinsically motivating and fulfilling work. The model initially postulated five 'core job dimensions' – skill variety (i.e., the use of different skills in a job), task identity (i.e., the possibility to complete a whole piece of work), task significance (i.e., the impact of the work on others' lives), feedback from the job (i.e., information about the own performance), and autonomy (i.e., the individual discretion to plan the work). These five core job dimensions operate through three psychological states – experienced meaningfulness, experienced responsibility, knowledge of results – on important work-related aspects of health like work motivation, job satisfaction, and low absenteeism. A recent meta-analysis (Humphrey et al., 2007) mainly supports these assumptions and adds further social and work context characteristics to the model.

Beyond work motivation, the Job Characteristic model also refers to basic processes of human action regulation, which especially benefit from autonomous goal setting and action planning and the accomplishment of complete tasks (e.g., Hacker, 2003). Thus from this model – just like the JDC model – it can be concluded that healthy work does not simply mean reducing job demands but rather setting the right demands.

Interventions to Reduce Occupational Stress

Individual-Level Interventions

Individual-level interventions target persons and change of individual behavior rather than work conditions. Thus, occupational stress according to the above mentioned stress models is usually not tackled, with few exceptions (e.g., Limm et al., 2011). Programs with the aim of better management of work stress are commonly called stress management interventions (SMIs). To date there is a large number of studies on the effects of SMI. A recent meta-review identified 27 meta-analyses and systematic reviews including 499 studies that examined the effects of SMI on common mental disorders (Bhui et al., 2012). Thus, there is a need to distinguish. SMIs can be classified in several ways:

Targets: In the context of work, individual stress management may be conceptualized as a program that focuses on change of behavior on different levels: A person may change work conditions, or personal appraisal of the conditions, or coping with emotional and physical reactions to the conditions (Ivancevich et al., 1990).

To give an example, a high effort and low reward situation can lead to stress reactions in the sense of emotional or cognitive irritation (Mohr et al., 2005), exhaustion, and sleep disturbance. To improve the situation, the affected person could try to decrease the effort or increase the reward by negotiating tasks and work conditions with managers

and colleagues. Alternatively, in a highly competitive profession, he or she could change appraisal and attitude by accepting the effort–reward imbalance situation as temporarily unavoidable and by perceiving the effort as a career strategy, which will lead to increased reward in the future (Siegrist and Marmot, 2004). Eventually, the person could use relaxation techniques or sports to counterbalance the stress reactions.

Intervention techniques: A common way to classify SMI is by the intervention technique. Interventions based on the principles of cognitive behavioral therapy (CBT) instruct participants about the role of their thoughts in eliciting stress reactions to stressful situations, and provide them with the skills to modify thoughts to better cope with stressful work conditions. Their main focus thus is the appraisal of the conditions, but CBT can as well support behavior change toward an active reducing of stressors or enhancing of resources. CBT-based SMI programs aim at empowering participants to actively manage stressful working condition. By this they differ from more passive relaxation or meditation techniques:

Interventions that focus on better coping with stress reactions are often based on the principles of muscle relaxation or meditation. They instruct participants how to reduce muscular tension, emotional arousal, or cognitive pondering due to work stress.

An alternative way is sports. Physical exercise may reduce stress reactions by distracting from the adverse conditions, enhance social support (if performed in groups), reduce muscle tension, stimulate endorphin production, and eventually strengthen emotional stability.

Other intervention techniques use a stress diary to write down, thereby verbalize and reflect stressful events, to identify causes of stress, to become aware of one's own reactions, and to set goals for managing stress.

Training practical skills as time management, problem solving, negotiating, or conflict resolution may reduce common sources of work stress. Interventions that teach more specific skill may serve to better handle stressful situations in special occupations, typically related to education, health services, or public security.

Level of prevention: Another way of conceptualizing interventions is by levels of prevention as primary, secondary, and tertiary prevention. Primary prevention interventions aim at influencing the sources of stress. Work design as an organizational approach of primary prevention is discussed below. However, also on the individual level the target of an intervention may be to alter work conditions. Secondary prevention interventions target stress reactions before they result in health problems. Tertiary prevention interventions target stress-related diseases as depression or anxiety; the approach could be early treatment or vocational rehabilitation (both are beyond the scope of this article). Most commonly SMIs are secondary prevention programs.

The duration of individual-level stress prevention programs usually ranges between several weeks and several months. Interventions may vary with respect to their intended outcomes, which can be psychological (well-being, mental health, etc.), physical (e.g., blood pressure, cortisol), or organizational (productivity, sick leave, presenteeism; work conditions, etc.).

Effectiveness of Individual-Level Interventions

Several recent systematic reviews and meta-analyses have attempted to synthesize the knowledge about the effectiveness of individual-level occupational SMIs (Bhui et al., 2012; Richardson and Rothstein 2008; Martin et al., 2009; LaMontagne et al., 2007; van Wyk and Pillay-van Wyk, 2010). Due to the large number and the considerable heterogeneity of studies, it is difficult to comprehensively summarize the evidence. As the cited reviews and meta-analyses have different aims and perspectives, their results are described separately before an overall conclusion is drawn.

Richardson and Rothstein (2008) included 36 experimental studies in a recent meta-analysis, analyzing 55 interventions with a total sample size of 2847 individuals. The average length of intervention was 7.4 weeks (range from 3 days to 7 months). Interventions were described as cognitive behavioral, relaxation, organizational, multimodal, or alternative. Most frequently, in 69% of interventions, relaxation interventions were tested. The effect of the SMI was measured by 60 different outcomes, mostly based on self-report. Typical outcomes included stress reactions, depression and anxiety, general mental health, and work satisfaction. Physiological outcomes were measured in a minority of studies, mostly by blood pressure registration. Organizational outcomes are even rarer, mostly measured as sick-leave days.

The overall weighted effect size (Cohen's d) for all studies was 0.526 (95% confidence interval 0.364, 0.687), which represents a significant medium to large effect. (The effect size is a statistical measure for the strength of an effect that facilitates comparison between different studies; as a convention, an effect size of 0.2 is regarded as small, 0.5 as medium, and 0.8 as big.)

Subgroup analyses showed that the largest effects were seen for interventions based on cognitive behavioral principles ($d = 1.164$; CI = 0.456, 1.871). If additional treatment components were added, the effect was reduced: The meta-analysis surprisingly finds that the more components were added to a cognitive behavioral intervention, the less effective was the outcome. Furthermore, multimodal in contrast to single component programs appear to lose effect with increasing treatment length.

Relaxation interventions were less effective; they constantly showed medium effect sizes ($d = 0.497$; CI = 0.309, 0.685). In the mixed group of 'alternative' interventions, studies that aimed at increasing participants' resources or management/job skills produced a combined significant large effect ($d = 1.414$, CI = 0.587, 2.241). These SMIs were designed to provide employees with individual tools to assist them to deal with the more stressful aspects of their work. With regard to specific outcomes, bias is introduced as the variables are likely to be chosen on the basis of the type of intervention: Thus the largest effects were found on psychological outcomes since CBT-based interventions only measured psychological, but no physiological outcomes, for which the overall effects were smaller. Productivity was the organizational outcome influenced most strongly.

Taken together, SMI that motivates the participants to actively manage their work stress by modifying or better handling it, or by changing their appraisal, seems to have stronger effects than passive coping with stress reactions by

relaxation, meditation, and alike. Targeted approaches in the sense of single component interventions have greater effects than multimodal multicomponent interventions. The effects are primarily seen in mental health (stress, depression, anxiety) and in productivity. Little is known about long-term effects. Furthermore, simultaneous assessment of various levels of outcome measures (psychological, organizational/process-orientated) in future studies can help to learn more about the mechanisms by which interventions reduce stress.

In a similar meta-analysis, Martin and colleagues (Martin et al., 2009) examined the impact of workplace health promotion programs that were evaluated by using a valid indicator or specific measure of depression or anxiety symptoms. They came to the conclusion that interventions that directly focused on mental health had positive but small effects on depression and anxiety, as did more unspecific, 'indirect' health promotion programs. However, they highlighted three studies with high above-average effects on mental health. These programs all used some kind of CBT approach.

Combining the results of 11 meta-analyses and 12 narrative reviews Bhui and colleagues (2012) draw a comprehensive picture of how SMIs at work influence anxiety, depression, and absenteeism. They confirm the findings outlined in the two meta-analyses cited above by showing that CBT-based SMI consistently produced the largest effect on these outcomes. The researchers could, however, not clearly state whether primary or secondary prevention is more effective and whether absenteeism can be influenced positively.

Systematic reviews for specific occupations were performed for health care workers and for policemen. In a Cochrane review, van Wyk and Pillay-van Wyk (2010) concluded that SMI seems to be effective to reduce job stress and prevent burnout in health care workers, mainly nurses, during the time of the intervention; however, there is insufficient evidence for the effectiveness beyond the intervention period. Thus, the overall effectiveness remains unclear. Similarly, Buchberger et al. (2011) conducted a health technology assessment evaluation studies on health promotion for nurses. They summarized that interventions for psychological health resulted in better stress management, more successful coping with workload, higher communication skills, and advanced training; however, the evidence is insufficient for a definite conclusion. For policemen, Peñalba et al. (2008) did not find studies that had sufficient quality to draw firm conclusions.

A systematic review addressing the socioeconomic results of preventive mental health promotion programs identified 47 studies worldwide. Especially for interventions at the workplace an economic return on investment was found (McDaid and Park, 2011). The cost–benefit ratio is of great importance, since SMI impose additional costs on employers or the health care system.

Implementation

It seems that only a small part of the recommended health care practices for prevention are implemented (Glasgow and Emmons, 2007). Several barriers have been identified as reasons, among them too demanding procedures for staff and participants, inflexibility, lacking alignment of organization and intervention, low participation or deficits in assessment or evaluation, just to name a few. Barriers can be manifold, but are most often found in the interaction of work setting and intervention in a lacking 'match.' An iterative closely intertwined process involving all partners in all stages of the process proposes a possible solution to this problem (Glasgow and Emmons, 2007). Hence, the integration of all stakeholders is essential for facilitating transfer and implementation as well as realization of measures (Driessen et al., 2010).

Organizational-Level Interventions

Organizational-level interventions (OLI) aim at the improvement of working conditions, i.e., the *structural* preconditions for health and well-being at the workplace. More specifically, according to the above introduced terminology, hindrance stressors shall be removed, a balance between challenge stressors and capabilities of employees shall be established, and job resources shall be maximized.

With that, OLI put specific emphasis on the primary prevention of disease (i.e., they eliminate stressful working conditions and establish job resources) but they also incorporate elements of secondary and tertiary prevention (i.e., they support more effective coping with stressful events, provide support, and help to minimize detrimental effects of existing health impairments). Due to its broad impact it is hypothesized that OLI are more effective than other approaches to maintain and improve the health and well-being of employees (LaMontagne et al., 2007).

Effectiveness of OLI

Although there is a strong emphasis on the implementation of OLI in occupational stress management systems, there are only few published studies on OLI with reasonable methodological quality, i.e., studies that used a control group to attribute observed effects on the intervention and not on confounding factors. Correspondingly, the evidence on the effectiveness of OLI is mixed: as cited above, Richardson and Rothstein (2008) conducted a systematic investigation of studies on controlled occupational SMIs. Out of the included 36 studies only 5 were OLI, which had a small and insignificant effect overall. LaMontagne et al. (2007) included 18 controlled interventions in their systematic review that exclusively targeted working conditions, or the interface between working conditions and the individual (see Appendix to LaMontagne et al., 2007). About two-third of these studies reported significant positive effects on favorable organizational level outcomes like autonomy or individual-level outcomes like stress reduction.

One reason for these inconsistent findings is that the effectiveness of OLI is highly sensitive to external disturbances, i.e., the same intervention can be highly effective in a supportive context but ineffective in an impedimental environment (i.e., Nielsen and Randall, 2012). This is because OLI often affect many organizational processes and structures and involves numerous stakeholders. Due to this complexity, there is the call for a more sophisticated evaluation of the intervention *process* beyond the mere evaluation of the intervention *effects* to reveal the mechanisms through which the intervention works (Nielsen et al., 2010).

The Implementation of OLI

Regardless of the specific target, the OLI process can be viewed as a cycle with the following critical phases: preparation, risk analysis, prioritization, development of measures, implementation of measures, evaluation, and improvement (e.g., healthy workplaces: WHO global model for action).

Intervention activities should be tailored to the specific needs and problems of the organization. This requires a *thorough risk assessment with established measures* (e.g., Nielsen and Randall, 2012). The adopted measures should capture the previously defined health-related working conditions with suitable scientific quality.

From the beginning *common goals and structured actions plans* need to be stipulated with all participants, as organizational stakeholders often have diverged interests and expectations in respect to OLI (e.g., work council vs management). As OLI frequently touch upon existing occupational areas of responsibility (e.g., occupational safety, quality management, health services, human resources management), implementation should be integrated into existing structures, as far as possible, to avoid redundancy and enable a sustainable implementation of organizational stress management measures.

Most importantly, OLI should only be introduced once *supervisor support* is assured. Of great importance is the structural integration of decision makers in a steering committee.

Participation of Employees

There are abundant approaches and procedures to conduct OLI. However, the indispensable core of all OLI should be the participation of employees: (1) Participation is a health-promoting factor in itself, because it accounts for a more fair organization of work processes and it strengthens employee competence. (2) Employees are experts in their work. Their participation increases the chance of adequate problem diagnosis as well as (3) the development of suitable and effective measures.

'Health circles' are one possibility of establishing participation during OLI (Aust and Ducki, 2004). Health circles are temporary work groups with employees that develop measures for the improvement of working conditions. There are first references for the effectiveness of participatory interventions like health circles (Aust and Ducki, 2004; Bourbonnais et al., 2011). However, there is substantial implementation effort of health circles that should be taken into account as a potential threat, especially so in cases of staff shortage and high workload.

Future Challenges

On the grounds of the knowledge summarized above open questions concern the sustainable implementation of effective occupational stress management into practice, the synergy between individual- and organizational-level approaches, and the long-term effects of occupational stress management on health, especially with respect to mental and cardiovascular diseases.

In the recent years an obvious change of work has occurred, which is, among others, marked by the global economic competition, rapid development of information technologies, blurred borders between time at work and leisure time, and a steadily increasing number of atypical work, like temporary contracts. Additional psychosocial risk factors for health and well-being may have emerged, which have not been considered sufficiently in the above-named classical organizational stress models. Hence, new conceptual and empirical models may be required to capture and systematize the ongoing changes of working and employment conditions and to allow forecasts of their effects on health and well-being.

The workforce in almost all industrialized countries is rapidly aging. Due to these demographic changes, it becomes more important to study occupational life-span models that enable healthy work careers and support employee's attempts to remain productive members of the workforce beyond the current retirement age. Moreover, due to the variety of aging processes, future work organizations have to create individually tailored solutions that enable older employees to compensate for specific age-related losses (e.g., health problems, decreased capacity of working memory) and to use age-related gains more efficiently (e.g., experience).

In conclusion, there is a clear imbalance between theoretical knowledge about the causes and processes of occupational stress on one hand and practical solutions to manage occupational stress on the other hand. To close this gap between theory and practice future research should therefore turn more intensively to the development and testing of effective occupational SMIs.

Abstract

Anthropologists continue to use broadly etched contrasts – equality versus hierarchy, gift exchange versus commodity sale – as abbreviations for complex differences between Melanesian social forms and cultural practices, and those of the modern West. These contrasts, although problematic, effectively highlight the transactional nature of Melanesian economies and polities, kinship and social organization; they similarly underscore the malleability of gender identity, personhood, and the body in Melanesia. Recent Melanesianist anthropology has given fuller attention to processes of colonial history and postcolonial change, including Christian missionization, the spread of capitalist markets, and nation-state formation. This research foregrounds the variety of local modernities and creative adaptations that Melanesians have produced since the nineteenth century out of their uneven and contested encounters with agents and institutions of exogenous origin.

The convention of dividing Oceania into three distinct geographic regions or culture areas – Polynesia, Micronesia, and Melanesia – originated in 1832 with the French navigator J-C-S. Dumont d'Urvilles. By this convention, Melanesia today encompasses the independent nation-states of Papua New Guinea, Solomon Islands, Vanuatu, and Fiji; the French overseas territory of New Caledonia (Kanaky); the Indonesian province of Irian Jaya or Papua (West Papua); and the Torres Straits Islands, part of the Australian state of Queensland. These islands comprise about 960 000 km^2 with a total population of more than eight million people. The large island of New Guinea and its smaller offshore islands account for almost 90% of the land area and 80% of the population of Melanesia (see Figure 1).

Melanesian Diversities

The diversity of contemporary Melanesian political arrangements is exceeded by a linguistic, cultural, ecological, and biological diversity that impressed early European explorers and challenged later social and natural scientists. Although mostly pig-raising root-crop farmers, Melanesians occupy physical environments ranging from montane rainforests to lowland river plains to small coral islands; they live in longhouses, nucleated villages, dispersed hamlets, and urban settlements. While racially stereotyped as black-skinned and woolly-haired people, they display a wide range of phenotypic features. Similarly, Melanesian social organizations illustrate numerous anthropologically recognized possibilities with respect to rules of descent, residence, marriage, and kin terminology. Melanesians speak more than 1100 native languages, some with tens of thousands of speakers and others with less than a few hundred. English, French, and Bahasa Indonesia are recognized as official languages; several pidgin-creoles are widely spoken and also recognized as official languages in Papua New Guinea and Vanuatu. Melanesia is thus culturally heterogeneous to the point that its very status as a useful ethnological category is dubious; many anthropologists would assign Fiji to Polynesia and classify Torres Straits Islanders with Australian Aborigines. Ethnographic generalizations about the region often show a marked bias toward cases from some areas (e.g., the New Guinea Highlands) rather than others (e.g., south-coast New Guinea), and in any case remain rare.

Linguists, archeologists, and geneticists offer persuasive narratives of prehistoric migrations that account for Melanesian heterogeneity. These narratives, although not universally accepted, reveal how Dumont D'Urvilles' convention obscures historical and cultural connections between Melanesian and other Pacific populations as well as fundamental differences within Melanesian populations. At least 40 000 years ago, human populations of hunter – gatherers settled the supercontinent of Sahul (Australasia), reaching what is today the island of New Guinea, the Bismarck Archipelago and the Solomon chain by at least 30 000 years ago. Linguistic evidence suggests that these settlers spoke Non-Austronesian (NAN or Papuan) languages, which today number around 750 and occur mainly in the interior of New Guinea, with isolated instances through the islands to the east as far as the Santa Cruz Archipelago. By 3500 years ago, a second migration out of Southeast Asia had brought another population into sustained contact with the original settlers of the Bismarcks. This migration is associated by archeologists with the distinctive Lapita pottery complex, distribution of which suggests that 'Lapita peoples' had by 3000 years ago moved as far south and east as hitherto uninhabited Fiji and western Polynesia. Lapita peoples spoke an early language of the Austronesian (AN or Malayo-Polynesian) family labeled Proto-Oceanic. Austronesian languages are today distributed along coastal eastern New Guinea and through island Melanesia; all Polynesian languages and most Micronesian ones are also descended from Proto-Oceanic. Hence the extraordinary linguistic, cultural, and biological diversity of Melanesia by comparison with Polynesia and Micronesia derives from at least two prehistoric sources: (1) processes of divergence and differentiation among relatively separated populations over the very long period of human occupation in the region, especially on the island of New Guinea and (2) processes of mixing or creolization between the original NAN-speaking settlers and the later AN-speaking arrivals in island Melanesia.

Figure 1 Islands of the South Pacific.

Social and Cultural Anthropology in/of Melanesia

Dumont D'Urvilles' classificatory legacy has been provocatively criticized on different grounds, namely that 'Melanesia' often designates one term of an invidious comparison with 'Polynesia.' Such comparisons, manifestly racist in many nineteenth-century versions, portray Melanesians as economically, politically, and culturally less developed than Polynesians and, by evolutionary extension, people of 'the West.' To Western political and economic interests, moreover, Melanesia has historically appeared marginal; Melanesianist anthropologists, for example, never found much support within the post World War II institutional apparatus of area studies. This marginality has rendered Melanesian studies as the exemplar of anthropology's authoritative discourse on 'primitives,' and contributed to the popular perception of Melanesian studies as the anthropological subfield most engaged in the contemporary study of radical (non-Western) Otherness. Such a perception not only turns Melanesian people into exotic vehicles for Western fantasy, but also suppresses the continuing history of colonialism in the region and misrepresents much Melanesianist anthropology, past and especially present.

Melanesian ethnography has played a central role in the history of the larger discipline's methods and theories. The work of W. H. R. Rivers on the 1898 Cambridge Expedition to the Torres Straits and later trips to Melanesia, and of Bronislaw Malinowski during his World War I era research in the Trobriand Islands, both mark important moments in the development of genealogical inquiry and extended participant observation as characteristic methods of social anthropology. Similarly, the Melanesian ethnography of M. Mead, G. Bateson, R. Fortune, and I. Hogbin, among others, guided anthropological approaches to questions of socialization and emotions, culture and personality, gender relations and sorcery, ritual process and social structure. From 1950 onwards, anthropology drew heavily on Melanesian ethnography – including the first waves of intensive fieldwork in the New Guinea Highlands – for diverse theoretical advances in the areas of cultural ecology, gender and sexuality, and in the study of metaphor, meaning, and knowledge transmission.

Gift/Commodity

Most prominent among the gate-keeping concepts that make Melanesia a distinctive anthropological place is exchange. Malinowski's classic description of *kula*, and Marcel Mauss's treatment of Malinowski's ethnography in *The Gift*, provided the grounds for understanding Melanesian sociality as fluid and contingent, performed through pervasive acts of give and take. In the 1960s, the critique of models of segmentary lineage structure in the New Guinea Highlands further enabled recognition of reciprocity and exchange as the Melanesian equivalents of the principle of descent in Africa. Exchange brings into

being the social categories that it perforce defines and mediates: affines and kin, men and women, clans and lineages, friends and trade partners, living descendants and ancestral spirits. The rhythms of Melanesian sociality thus develop out of infrequent large-scale prestations associated with collective identities and male prestige; occasional gifts of net bags from a sister to her brother or of magic from a maternal uncle to his nephew; and everyday exchanges of cooked food between households and betel nut between companions.

Before contact with Westerners, Melanesia was laced by extensive trade networks that connected coastal and inland areas, and linked numerous islands and archipelagoes. These regional networks crossed different ecological zones and organized the specialized production of food, pigs, crafts, and rare objects of wealth such as pearl shells and bird plumes. Wealth objects were in turn often displayed and circulated in sequential chained exchanges, of which the most complex and geographically far-reaching include *kula*, and the Melpa *moka* and Enga *tee* systems of the central New Guinea Highlands. These exchange systems often define a sphere of male-dominated activity that depends on the labor of women, but instances of women circulating women's wealth in public exchanges do occur throughout Melanesia. During the colonial period, many trade networks atrophied, while other forms of competitive exchange effloresced, incorporating new items of wealth. State-issued money now commonly circulates in exchange alongside indigenous currencies and wealth, especially as part of marriage payments and homicide compensations.

Melanesians sometimes self-consciously contrast their own reciprocal gift-giving with the market transactions of modern Western society; for example, the distinction between *kastam* ('custom') and *bisnis* ('business') occurs in the English-based pidgin-creoles of the region. In related fashion, anthropologists have used an ideal – typical contrast between a gift economy and a commodity economy to describe the social relations of reproduction characteristic of indigenous Melanesia. For Gregory (1982), 'gift reproduction' involves the creation of personal qualitative relationships between subjects transacting inalienable objects, including women in marriage; and 'commodity reproduction' involves the creation of objective quantitative relationships between the alienable objects that subjects transact. This dichotomy provides a way of talking about situations now common in Melanesia in which the status of an object as gift or commodity changes from one social context to another, and varies from one person's perspective to another. Such situations occur, for example, when kin-based gift relations become intertwined with the patronage system associated with elected political office or when marriage payments become inflated by cash contributions derived from wage labor and the sale of coffee and copra.

While Gregory's formulation has been criticized as obscuring the extent to which commodity-like transactions – barter, trade, localized markets – were always a feature of Melanesian social life (and gifts a feature of highly commoditized Western societies), it nonetheless highlights how Melanesians produce crucial social relations out of the movement of persons and things. Anthropologists have thus used the concept of personhood as a complement to the concept of the gift in understanding Melanesian moral relationships; for it is in the context of gift exchange that the agency of persons and the meaning of things appear most clearly as the effects of coordinated intentions. Marilyn Strathern contrasts a Melanesian relational person or dividual with a Western individual. Whereas Western individuals are discrete, distinct from and prior to the social relations that unite them, Melanesian dividuals are composite, the site of the social relations that define them. Similarly, whereas the behavior of individuals is interpreted as the external expression of internal states (e.g., anger, greed, etc.), the behavior of dividuals is interpreted in terms of other people's responses and reactions. The notion of dividuality makes sense of many Melanesian life-cycle rites that recognize the contributions of various kin to a person's bodily growth, as well as of mythological preoccupations with the management of ever-labile gender differences.

Equality/Hierarchy

Melanesian polities have often been characterized as egalitarian relative to the chiefly hierarchies of Polynesia; instances of ascribed leadership and hereditary office, numerous throughout insular Melanesia, have accordingly been regarded as somewhat anomalous, while the categorical distinction between 'chiefs' and 'people of the land' has served to mark Fiji's problematic inclusion within Melanesia. Traditional Melanesian political organization has been defined negatively, as not only stateless but also lacking any permanent form capable of defining large-scale territorial units. Precolonial warriors, such as those of south-coast New Guinea, distinguished themselves through vigorous practices of raiding, head-hunting, and cannibalism that ensured social and cosmological fertility. Local autonomy, armed conflict, and ongoing competition among men for leadership have thus been taken as the hallmarks of traditional Melanesian politics. This definition of precolonial Melanesian polities invokes a sharp contrast with the centralized, bureaucratic, violence-monopolizing states of the West. Yet, at the same time, Melanesian politics, epitomized in the figure of the self-made 'big man,' have sometimes been thought to recall values of individualism and entrepreneurship familiar from the West's own self-image.

Big men typically validate their personally achieved leadership through generous distributions of wealth. They manipulate networks of reciprocal exchange relationships with other men, thus successfully managing the paradox of generating hierarchy – even if only temporarily – out of equality. This paradox is variously expressed within Melanesia. In classic big-man exchange systems, known best from areas of high population density and intensive pig husbandry and horticulture in the New Guinea Highlands (Melpa, Enga, Simbu, Dani), a constant and imbalanced flow of shells, pigs, and money underwrites individual prestige. Such systems are not found everywhere in Melanesia, however, prompting Godelier (1986) to invent a new personification of power, the 'great man.' Great men emerge where public life turns on ritual initiations, where marriage involves the direct exchange of women ('sister exchange'), and where warfare once similarly prescribed the balanced exchange of homicides. The prestige and status of great men often depends upon their success in keeping especially valued 'inalienable possessions' out of general

circulation. While this typological innovation has been challenged, political life in the Sepik area and in eastern Melanesia frequently involves transmitting ritual resources (heirlooms, myths, names, and so forth) within a delimited kin grouping such as a clan. In the Mountain Ok area, ancestral relics (bones and skulls) provide the material focus of a secret men's cult that links contiguous communities and complements clan affairs; in insular Melanesia, forms of voluntary male political association detached from kin groupings are found, such as the public graded societies of northern Vanuatu. Nevertheless, the scope for establishing political relations in precolonial Melanesia was restricted by the instability of big men's exchange relations, or by the demands placed on high-ranking men to sponsor youthful aspirants, or by the limited extent of the communities or kin groups beyond which ritual resources have no currency.

Whereas Melanesian political relations have been deemed egalitarian by comparison with the West, gender relations have usually been characterized as manifestly inegalitarian. Ethnography of highlands New Guinea in particular suggests that women's productive labor in gardening and pig husbandry is eclipsed if not wholly appropriated by men who act exclusively as transactors in public exchanges. In areas with once secret and lengthy rites of male initiation, senior men socialized boys into ideologies of dangerous female power and pollution while enforcing strict physical separation of the sexes. Ethnography of insular Melanesia (AN speakers), by contrast, suggests that gender inequality is less severe, tempered by women's social and genealogical roles as sisters rather than wives, and as both producers and transactors of cosmologically valued wealth items such as finely woven mats. But Margaret Mead's pioneering work on sex and temperament in the Sepik area, and Knauft's (1993) review of south-coast New Guinea ethnography suggest the extreme variation possible in gender relations among even geographically proximate societies.

New forms of social inequality and hierarchy have taken shape since the mid-nineteenth century through intensified interactions with foreign traders, missionaries, and government officials. During the colonial period, 'chiefs' were often appointed in areas where they had not existed, while indigenously recognized leaders were often able to use their status to monopolize access to the expanding cash economy. Male labor migration put extra burdens on women who remained at home, their contacts with new ideas and values inhibited. In rural areas today, 'rich peasants' have emerged by manipulating customary land tenure – and sometimes using 'development' funds of the postcolonial state – to accumulate smallholdings of cash crops; conflicts have arisen over claims to cash crops that women raise on land owned by their husbands. In urban areas, political and economic elites attempt to reproduce their dominant class position through private education and overseas investments as well as cosmopolitan consumption practices.

Melanesian Modernities

The legacies of different colonial states (Great Britain, France, Germany, The Netherlands, Australia, and Indonesia) variously condition Melanesian political economies, especially with regard to control of land. In Papua New Guinea, limited land alienation by the crown, an indirect subsidy of contract labor, has preserved a vital resource in the defense against encroaching commodification; but French settlers in New Caledonia and, more recently, Javanese transmigrants in Irian Jaya violently displaced indigenous populations. In Fiji, complicated arrangements for leasing agricultural land, a consequence of British colonial policy, generate tension between Fijian landowners and their largely Indo-Fijian tenants, descendants of indentured plantation workers brought from India in the late nineteenth and early twentieth centuries. In addition, uneven capitalist markets and proliferating Christian denominations have added new dimensions to the diversity of Melanesia. Anthropologists readily acknowledge that even in those parts of Melanesia where the presence of foreign agents and institutions has been relatively weak (once a tacit justification for rendering colonial entanglements ethnographically invisible), received cultural orientations have become articulated with globalized elements of Western modernity. In other words, Melanesia is emerging as a key anthropological site for the comparative study of plural or local modernities.

Current Melanesianist research, historical as well as ethnographic, extends earlier studies of north-coast New Guinea cargo cults that sought to demonstrate how indigenous cosmologies shaped local interpretations of European material wealth and religious culture. This research highlights the syncretic products of intercultural encounters, noting how Melanesians have appropriated and reinterpreted such notable ideological imports as Christianity, millenarian and otherwise, and democracy. Even the impact of large-scale mining and timber projects has been shown to be mediated by highly local understandings of land tenure, kinship, and moral economy. In West Papua and Papua New Guinea, these projects define sites of struggle among transnational corporations, national states, and local stakeholders, often generating destructive environmental consequences (the Ok Tedi and Grasberg gold mines) and massive social dislocation (the civil war on Bougainville).

By the same token, current research emphasizes how the historical encounter with Western agents and institutions often transforms indigenous social practices, including language socialization, thus revaluing the meaning of tradition. For example, the flourishing gift economies of rural villagers are often a corollary of the remittances sent back by wage workers in town, while the ritual initiation of young boys might provide a spectacle for paying tourists from Europe and the USA. Since the 1970s, the emergence of independent nation-states has stimulated attempts to identify national traditions with habits such as betelnut chewing or artifacts such as net bags, both of which have become much more geographically widespread since colonization. In many of these states, 'chieftainship' furnishes the newly traditional terms in which elected political leaders compete for power and resources. In New Caledonia, the assertion of a unifying aboriginal (Kanak) identity and culture has been a feature of collective anticolonial protest.

Contemporary Melanesian societies and cultures are thus defined by a tense double process. On the one hand, they are increasingly drawn into a world system through the spread of commercial mass media; the force of economic reforms mandated by interstate regulatory agencies; and the sometimes tragic exigencies of creating political communities on the global model of the nation-state. On the other hand, they

continue to reproduce themselves in distinctive and local ways, organizing processes of historical change in terms of home-grown categories and interests.

Abstract

The terms 'Polynesia' and 'Micronesia,' nineteenth-century European inventions, have survived as convenient labels to refer to two large regions of the insular Pacific. These regions were peopled in the last 4000 years by waves of seafaring immigrants from Southeast Asia, who established patrilineal societies in Polynesia and matrilineal societies in Micronesia, which exhibit various degrees of stratification. The intensification of contacts with Westerners during the Enlightenment heralded an era of colonialism that brought about radical transformations. With few exploitable resources, contemporary societies of Polynesia and Micronesia tackle problems that range from deteriorating health to the possible effects of global warming.

History of Geographical Nomenclature

The region that has commonly been referred to as 'Oceania' since the early nineteenth century was peopled by successive waves of prehistoric settlers. The last of these were a seafaring people who settled in the islands of the Pacific, mingling with prior occupants in the case of New Guinea and neighboring areas and occupying uninhabited islands further west, all the way to Hawai'i in the Northern Pacific, New Zealand in the far south, and Easter Island in the southeast corner of the region. The social and cultural similarities among the islands east of and including Fiji reflect not only their relatively recent peopling by the same people but also the fact that islanders maintained active contact with one another throughout prehistory, even across vast distances, thanks to their sophisticated navigation technology. For them, the Pacific represented not a vast ocean dotted with minuscule islands, but rather a 'sea of islands,' in the memorable phrase of Tongan scholar Hau'ofa (1994), namely a vast network of human settlements connected to one another through kinship, exchange, alliance, history, and cosmology.

In 1756, French scholar and politician Charles de Brosses coined the term 'Polynesia' to refer to all islands of the Pacific east of Australia, hoping to persuade the French court to finance their exploration and eventual colonization, convinced as he was that they would prove to be 'rich in spices.' The label remained standard in European writings for several decades, during which Europeans began to take a keen interest in the Pacific Islands. Explorers, as well as their contemporaries who read and commented on the journals of their voyages that they published to great acclaim, were informed by the humanistic universalism of the Enlightenment and early Romantic eras that viewed humanity as one. They saw 'primitive man' as a model for humanity, living in harmony with nature and one another, and unencumbered by the trappings of 'civilization.' In particular, Tahiti and the Society Islands figured prominently in the elaboration of this romantic primitivism after first contact with British and French navigators in 1767 and 1768, respectively.

The early nineteenth century witnessed a radical shift in the European philosophical climate, particularly in France, with the emergence of a preoccupation with racial difference, which was now viewed as evidence of the polygenetic origin of humans and of the evolutionary inequality among them. It is in this racialist context that two French navigators with scholarly aspirations, Jules Dumont d'Urville and the lesser-known Grégoire-Louis Domeny De Rienzi, simultaneously devised a typology of Pacific Islanders based on their physical appearance, particularly skin color, and a division of the Pacific Islands into three large regions (in addition to a fourth one, 'Malaysia,' applied to insular southeast Asia): Melanesia (i.e., dark islands), Micronesia (i.e., small islands), and Polynesia (i.e., many islands), the referent of the latter being now much reduced in size. The different preoccupations of European observers of Pacific Islanders at different times are inscribed in the historical evolution of maps (Tcherkézoff, 2008) and iconographic representations (Smith, 1985/1969). At the time of contact, islanders themselves referred to their homes with names for individual islands if they were small enough or, in the case of larger islands, with the names of specific villages, regions, or language groups. Many of these toponyms were varied, complex, and contested.

Polynesia and Micronesia as Cultural Areas

Despite the morally problematic historical foundation of this nomenclature, 'Polynesia' and 'Micronesia' have remained to this day convenient labels for geographical areas whose social, cultural, archeological, historical, political, and linguistic significance is somewhat arbitrary. Polynesia and Micronesia are complementary to Melanesia, generally considered to comprise New Guinea and adjacent islands, the Solomon Islands, New Caledonia, and Vanuatu.

Micronesia encompasses Palau and outlying islands, Guam, the Mariana Islands, Caroline Islands, Marshall Islands, and Gilbert Islands, as well as two isolated islands, Nauru and Banaba (Ocean Island). Contemporary political considerations may include island groups of the Central Pacific like the Phoenix and Line Islands; although geographically located in Polynesia, these islands, which were not permanently inhabited until the modern age, are governed by Kiribati, the modern state based in the Gilbert Islands.

Polynesia includes all islands and groups falling within a large triangular area whose apexes are New Zealand to the south, Hawai'i to the north, and Rapanui (Easter Island) to the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12121-X

west. The largest islands and island groups of the region are Tonga, Samoa, Rarotonga and the Southern Cooks, Tahiti and the Society Islands, the Marquesas, and Hawai'i, in addition to the much larger New Zealand. Fiji and Rotuma are sometimes considered part of Melanesia and other times part of Polynesia. Politically or culturally notable smaller islands include Niue, Wallis and Futuna, Tuvalu, Tokelau, the Northern Cooks, Rapanui, and Pitcairn Island, as well as the Tuamotus, Austral, and Gambier Islands, which are politically subsumed under French Polynesia. In addition, a geographically heterogeneous group of about 18 islands and sections of islands are commonly identified as 'Polynesian Outliers' societies because they are located outside of this triangular area: in Melanesia to the west (e.g., Takuu off Bougainville Island, Sikaiana and Rennell in the Solomon Islands, Mae and Mele in Vanuatu, North and South Ouvea Atoll in the Loyalty Islands) and, in the case of two islands (Nukuoro and Kapingamarangi), in Micronesia.

Islands of many different types are found in the two regions: a few continental islands (e.g., Guam); volcanic structures, some of which can be substantial in size (e.g., Hawai'i); raised coral islands of different types (e.g., Tonga); atolls (e.g., Tuvalu); and combinations of these. These various morphological structures, combined with a vast array of climatic conditions (from subarctic to equatorial climates, from wet to dry), provided prehistoric settlers with very different problems of ecological adaptation.

The human groupings that inhabited each of the two regions at the dawn of contact with Europeans shared a number of social and cultural characteristics with one another, and continued to do so well into the modern age. Yet many societies of insular Melanesia display characteristics that are identical to those prevalent among Polynesian or Micronesian societies, reflecting the fact that all three regions were settled by the same people in prehistoric times, even though the newcomers found already inhabited land in the Western part of Melanesia. In addition, commonalities among the societies of both areas are balanced by important patterns of variation, to the extent that no feature of social organization of culture will be found in all societies in question.

Perhaps the least controversial way of identifying Polynesia is linguistically: all languages spoken natively in the islands are more closely related to one another than to any other language. Indeed, the reason for identifying Outlier societies as Polynesian is the fact that all their members speak languages that are most closely related to the languages spoken in Polynesia. In terms of social organization and culture, however, Outlier communities vary widely, from bearing considerable similarity to the rest of Polynesia (e.g., Tikopia) to having much more in common with their more immediate non-Polynesian neighbors (e.g., the Polynesian-speaking villages of Ouvea, Loyalty Islands). Yet even this criterion is not devoid of caveats: on the boundary between Fiji and Tonga, historical linguistic evidence suggests a continuum of gradual linguistic differentiation rather than a clean break. In contrast, linguistic factors are of little use as determiners of what Micronesia includes and what it does not: all languages spoken in the area are Austronesian, but some (e.g., Chamorro of the Marianas and Palauan) are closer to languages spoken outside of Micronesia (e.g., in the Philippines) than to the other languages of Micronesia.

Contemporary Polynesian and Micronesian societies can only be understood with reference to the fact that many became diasporic in the course of the second half of the twentieth century, a trend originally motivated by labor migration to the industrial centers of the Pacific Rim. Today, one finds in New Zealand significant communities of Samoans, Tongans, Niueans, and Cook Islanders; Samoans and Tongans are also settled in comparatively large numbers in Australia; both are also represented in Hawai'i and the Continental United States, where Caroline and Marshallese Islanders are also numerous, at least in comparison with the size of the populations in the island groups of origin. Emigrant communities in many cases are much more populous than the island-based communities. While the Cook Islands and Niue, two small Polynesian states partially under New Zealand's political jurisdiction, have 19 000 and 1400 inhabitants, respectively, Cook Islanders living in New Zealand number 58 000 and Niueans 22 000 (2006 figures). Micronesian and Polynesian people also migrate internally to urbanized or industrialized centers of the Pacific Islands. Thus Guam, New Caledonia, Fiji, and Hawai'i are home to many Pacific Island migrant communities originating from surrounding island groups.

Initial Human Settlement

Around 3500 BP, a wave of people traveled from East and Southeast Asia, settling in the islands of Melanesia, some of which were already inhabited while others were not, and occupying the entire insular region in a relatively short time (3500–1000 BP). While the process inevitably involved backtrackings, sidesteps, and false starts, its general West-to-East direction is reflected in the relative heterogeneity of cultures, social structures, and languages in the Western Pacific compared to the relative homogeneity of societies and languages further east.

The most salient archeological evidence for this conjectured prehistoric migration is a lowly style of decorated pottery referred to as 'Lapita,' fragments of which are found in insular Melanesia and Western Polynesia, carbon-dated to 3500–2000 BP. Lapita pottery makers and users appear to have been accomplished long-distance sailors who utilized large outrigger sailing canoes, skilled fisherfolk, and agriculturalists of staples that they brought with them, such as taro, believed to be among the first food crops ever to be domesticated (around 10 000 BP in tropical Asia). Among other sources of food that they may have transported on their long voyages figure pigs, dogs, and fowl. They organized their social life in hierarchical fashion. They spoke languages that belonged to the Austronesian language family, the largest in the world in terms of its geographical spread and number of different languages, with daughter languages spoken today from Madagascar to Easter Island, including Indonesia, Malaysia, and the Philippines. With few exceptions (such as the languages of Western Micronesia mentioned earlier), languages of these regions all belong to the Oceanic group of Austronesian.

Around 3000 BP, the settlers reached Fiji, Tonga, and Samoa, an area in which, according to some researchers, migrations may have 'paused' for a while. Such a pause would have allowed a social, cultural, and linguistic distinctiveness

to emerge that would eventually become what is now recognized as 'Polynesian.' From the Fiji–Western Polynesia area, early Polynesians settled the rest of Polynesia in the course of the following two millennia, finally reaching Hawai'i in about 650 AD and New Zealand around 1000 AD (Kirch, 2000). There is no convincing evidence of any subsequent prehistoric human settlement in the insular Pacific other than the Lapita potters and their descendants (particularly from south America), although they intermarried in Melanesia with their non-Lapita-making neighbors, forming as diverse a genetic pool as is found in any other part of the world.

Micronesia's prehistory is much more complex than that of Polynesia, and less well understood. Evidence of human settlement in the Mariana Islands dates back to approximately 4000 BP. The archeological record indicates a Southeast Asian connection for this early population, as does archeological evidence gathered on Palau and Yap. The rest of the Caroline Islands, the Marshall Islands, and the Gilbert Islands were settled by a northwestward back-migration from eastern Melanesia. Languages spoken in this region, commonly referred to as 'Nuclear Micronesian,' exhibit greater linguistic homogeneity than other Micronesian languages, suggesting a more focused history of prehistoric settlement.

Society and Culture

Many aspects of precontact society and culture have reproduced over time and continue to characterize contemporary circumstances. In precontact times, the societies of Polynesia and Micronesia displayed certain degree of sociocultural commonality, as witnessed, for example, in a tendency to have stratified political systems and in the elaboration of certain symbolic complexes such as *tapu* (roughly, 'religion-based prohibition') and *mana* (roughly, 'efficacy of divine origin') in Polynesia (Howard and Borofsky, 1989). However, the recognition of patterns of commonality must always be qualified in at least two ways. First, one must be attentive to the dynamics through which certain characteristics have come to be identified as 'typically' Polynesian or Micronesian in spite of the fact that these characteristics are absent in some societies of the region. Second, 'precontact times' is a vague characterization at best, and all island societies experienced radical changes over the centuries, some of which can be identified archeologically, in the course of which 'typical' Polynesian or Micronesian characteristics appeared in and disappeared from particular societies.

A significant number of societies in both regions were socially and politically stratified, the more so in Polynesia than in Micronesia. Particularly on large islands and island groups, chiefdoms were organized around a leadership that derived power through a combination of genealogical ties to both sacred and profane entities that confirmed claims to power (ascription) and personal performance that hopefully confirmed these claims (achievement). In some of more stratified societies, persons were also ranked into categories ranging from the highest ranks, which were commonly sacralized, to the lowest ranks, whose members were often not considered human. Other societies, in contrast, displayed little stratification and emphasized egalitarianism and consensual decision making. Political organization on some islands was centered on localized kinship units, particularly in Micronesia but also on the smaller islands of Polynesia. The rough correlation between the amount of resources to be produced and organized and the degree of social stratification, at least in Polynesia, led some early researchers to propose that one engenders the other: chiefs, as resource managers, increase in importance as resources increase in volume (Sahlins, 1958). Few anthropologists today would give such determinative power to resource management (and indeed the empirical evidence does not support the model), although it certainly plays a role in the development and elaboration of social stratification.

Prevalent patterns throughout the area centralized the identification of a common founding family ancestor, creating in some societies a pyramid-shaped kinship structure. In Polynesia, the most important branch was the senior patrilineal branch, and members of other branches reckoned their relative status according to their relative distance from the main descent branch, measured through relative patrilineality and seniority, although matrilineal descent could also play an important role. Micronesian societies are predominantly matrilineal. There, matrilineal clans have historic claims to particular pieces of land and are the basis for social organization, with rank being based on claims of founding settlement of particular pieces of land. Probably all Polynesian and Micronesian societies also offered the possibility of bilateral affiliation, whereby kinship could be based on either patrilineal or matrilineal principles, thus providing room for social and political maneuvering. Adoption in its various guises was and continues to be prevalent throughout Polynesia and Micronesia.

Throughout Polynesia, gender figures prominently in the reckoning of rank, although the specifics of this interaction differ across societies. In Samoa and Tonga, for example, the relationship between sisters and brothers is foundational to the cultural and social organization of society, with sisters being superior in rank to brothers, particularly if senior to them. However, the prevailing ideology throughout the region dictates that the husband is the head of the family, including his wife, although the extent to which this ideology is the result of nineteenth-century missionaries' reconfiguration of the Polynesian family is not known. At first contact with Europeans, Tahitian society included a category of transgender males that took some aspects of women's identity, which is now widespread throughout Polynesia, but less obviously so in Micronesia (Besnier and Alexeyeff, 2013).

Early Contacts with Europeans and Colonialism

While Pacific Islanders maintained active contacts between islands and island groups prior to establishing contact with Westerners in the region, Europeans' arrival and gradual colonial domination over the islands brought about fundamental changes. Spanish, Portuguese, and Dutch travelers had sailed through Polynesia and Micronesia since the very early days of the Age of Discovery, but their contacts with Islanders were sporadic, ephemeral, and often violent. The exception to the first two characteristics (but not the third) are Guam and the Marianas, which Spaniards saw as strategically situated on

the sea road between the colonial centers of the empire in the Philippines and the New World. Spain claimed these islands in the mid-sixteenth century (later extending its claim over the rest of Micronesia), a move which was followed by the virtual decimation of the Chamorro inhabitants of Guam and the Marianas through disease, slaughter, and forced resettlement.

Contacts between Westerners and Islanders in both Polynesia and Micronesia did not begin in earnest until the end of the eighteenth century, when the relatively peaceful period following the end of the Seven Year War in Europe (1763) enabled France and Britain to fund expeditions to the Pacific Islands and other parts of the world. These voyages were driven by complicated, overlapping, and sometimes contradictory motivations, including the desire to find lands hitherto unknown to Europeans and exploit the resources they might offer (particularly the conjectured *Terra Australis Incognita* or 'unknown land of the South'), the intellectual curiosity that reigned during the European Enlightenment, and scientific endeavors, the most celebrated being the mapping of the transit of Venus from Tahiti, which secured funding for Captain James Cook's first voyage around the world (1768–71).

Enlightenment-era contacts were considerably more peaceful than those of earlier centuries. Still, despite the ideals of the Enlightenment that suffused them on the European side, different perceptions of what these contacts were about, particularly different ideas about property, did occasionally lead to serious conflicts. Perhaps the most celebrated from the Westerners' perspective is Captain Cook's violent death on the Big Island of Hawai'i, the analysis of which became the topic of a spirited intellectual exchange in the 1990s between two prominent anthropologists about whether or not Hawaiians viewed Cook as a god (Sahlins, 1987; Obeyesekere, 1992). But even when islanders did not suffer casualties at the moment of contact, in many parts of Polynesian and Micronesia they subsequently suffered from the new diseases, economic upheavals, wars, land dispossessions, outright massacres, raids by slavers, and other calamities that were associated, directly or indirectly, with the increasing Western dominance over the region. Some scholars in the nineteenth century expressed concern over the possible complete disappearance of Pacific Islanders, a sentiment echoed in the twentieth century in the 'fatal impact' approach to early contacts advanced by some historians (Moorhead, 1987).

Early European travelers to the Pacific Islands were soon followed by a broad variety of Westerners, including adventurers, traders, whalers, and employees of colonial corporations seeking to establish plantations and trading empires. Those whose impact was most consequential were missionaries of various Christian denominations, particularly adherents of the nonconformist evangelical movements that were then sweeping Britain in the late eighteenth century. They later competed with Catholic missionaries (who had been firmly implanted in Guam since the sixteenth century) and Mormons, who first arrived in the Tuamotu Islands as early as 1844. Members of the London Missionary Society, founded in 1795, arrived in Tahiti in 1797 and, after some vicissitudes, managed to convert a chief whose power had been greatly increased by his direct contact with earlier European visitors. In the socially stratified societies of Polynesia, the strategy of first converting the powerful with the rest of the population following suit led to swift and effective conversions. Today, all islanders adhere to some form of Christianity, with different denominations often competing for adherents.

A notable consequence of Westerners' increasing visibility in nineteenth century Polynesia was the consolidation of hitherto politically fragmented chiefdoms. In Tonga, Fiji, Tahiti, and Hawai'i (and to a lesser extent Samoa and New Zealand), ambitious and astute chieftains utilized the new tools that Westerners introduced to the islands, trading natural resources for firearms and protection for religious conversion, to defeat their competitors and impose their rule over entire islands and island groups, establishing themselves as sovereigns. The emergence of these societies in the modern age was accompanied by radical reconfigurations of power structures, with the introduction of new forms of inequality but also emergent notions of citizenship protected by constitutions. Of the kingdoms established in the nineteenth century, only Tonga remains to this day, others having fallen to the imposition of colonial rule. The most egregious case was the illegal overthrow by the United States of the Hawaiian monarchy in 1893 with the pretext of protecting the interests of American plantation owners.

In the course of the nineteenth century, European powers and later the United States sought to establish colonies and spheres of influence, competing over the richer islands (e.g., Tahiti, New Zealand, Samoa), while annexing island groups with few or no exploitable resources in the context of international treaties designed to regulate their spheres of influence. In Polynesia, the key players in the nineteenth century were predominantly British, French, and German. Beginning in 1842, France established a protectorate, and later colony, over Tahiti and numerous adjacent islands. Māori chiefs in New Zealand were made to sign the infamous Treaty of Waitangi with Britain in 1840, the consequences of which are still argued over to this day. The Cook Islands became a British protectorate in 1888, the administration of which was transferred to New Zealand in 1901. In 1900, the British consul essentially forced King George II of Tonga to sign a treaty that made the kingdom a protected state of Britain. The Tripartite Convention of 1899, signed by Germany, the United States, and Britain, placed the larger islands of Samoa under German control, while the US Navy took over the administration of the smaller eastern islands of the group, which have been known as American Samoa to this day.

In Micronesia, Spain hung on to the last significant remnants of its colonial empire until its defeat in the Spanish–American War of 1898, when Guam came under US control (along with, outside the region, the Philippines and Puerto Rico, while Cuba became independent under the control of the US). A German–Spanish Treaty in 1899 added to the German empire the Caroline, Mariana, and Marshall Islands, as well as Palau and Nauru.

During these transformative decades, several pioneering scholars documented the societies and cultures of the two regions. Polish-born John Stanislaw Kubary (1846–96), for example, who eventually became an employee of the Hamburg-based plantation firm Godeffroy und Sohn (as well as an Australian citizen), wrote detailed accounts of the Micronesian societies among which he lived. German-educated Russian aristocrat Nikolai Mikloukho-Maclay (1846–88), who

also settled in Australia, documented Micronesian as well as New Guinea societies and championed Pacific Island people against colonial exploitation. Their important descriptive works have been largely forgotten because of their authors' short lives and the fact that they wrote in Polish and Russian, respectively. Slightly more enduring are the detailed works about Palau, Samoa, and Hawai'i of German ethnologist Augustin Krämer (1865–1941).

The end of World War I somewhat reshuffled the distribution of colonial powers, with Western Samoa passing into the hands of New Zealand after Germany's defeat. Japan, an ally of Britain and France at the time, emerged as a colonial power, being granted by the League of Nations in 1920 a South Pacific Mandate (*Nan'yō-chō*) over previously German-controlled Micronesia. During the two-and-a-half decades of Japanese rule, Micronesia experienced an influx of labor migrants, who came to work on plantations, in mines, and in fishing ventures, and eventually numbered more than twice the number of native Micronesians (approximately 100 000 immigrants for 40 000 Micronesians). The fact that most came from the former southern kingdom of Okinawa, which Japan had annexed 4 years after the 1868 Meiji Restoration, meant that they shared a colonial master with Micronesians, with whom many established cordial relations. Japanese rule and the Okinawan migration that it enabled left a strong cultural imprint on Micronesia.

World War II had a dramatic effect on all of Micronesia, which, with Melanesia, was the stage of some of the fiercest battles of the Pacific Theater. Micronesian lives were profoundly affected by the conflict and its aftermaths (Poyer et al., 2001). In contrast, Polynesia (other than Pearl Harbor in Hawai'i) remained largely in the background of the conflict. At the end of World War II, the United Nations created a Trust Territory of the Pacific Islands over all of Micronesia except the Gilberts, Nauru, and Guam, which the United States administered from 1947. The American administration took great pains to obliterate prior Japanese influence. Piggy-backing on the military administration, American anthropologists made Micronesian societies and cultures into the object of sustained research (Kiste and Marshall, 1999), studiously ignoring the substantial ethnographic corpus produced by Japanese anthropologists in prior decades, which to this date remains largely unknown outside of Japan.

Decolonization

The worldwide decolonizing trends of the second half of the twentieth century affected the entire Pacific Island region, as island nations began obtaining their independence from world powers. In Polynesia, Western Samoa (now Samoa) was granted independence in 1962, and Tonga ceased to be a British protected state in 1970. Decolonization in island groups held by the United States and France (particularly Micronesia and French Polynesia, respectively) was and still is a slower, more complex, and conflict-ridden process. A notable factor in both cases was the nuclear tests that both powers conducted in the islands until well into the 1990s, which created economic booms but also fundamental transformations in the lives of people, including ecological and health problems for the affected populations (Johnston and Barker, 2008).

Today, France continues to maintain a colonial presence in French Polynesia and Wallis and Futuna (both Polynesian groups), which is contested in the former but receives general local approbation in the latter. The United States signed a Compacts of Free Association with the Federated States of Micronesia and the Marshall Islands in 1986 and with Palau in 1994, and since then these entities have been recognized as sovereign nations despite continuing US security interests in the islands. American Samoa and Guam are unincorporated US territories in which the federal government maintains control of many functions, in spite of some local opposition in the case of Guam. The Northern Mariana Islands became a Commonwealth of the United States in 1986, whose citizens hold US citizenship but whose government controls internal affairs, although the extent of this control has been the subject of complex negotiations.

Rapanui (Easter Island) has been administered by Chile since 1888, despite political tension, and tiny Pitcairn Island (Polynesian from a geographical point of view) by Britain. New Zealand holds special political ties with three self-governing territories, namely Niue, Tokelau, and the Cook Islands. Hawai'i, which became the 50th state of the United States in 1959, and New Zealand are both postcolonial entities in which the politics of indigeneity are tense: indigenous Hawaiians and New Zealand Māori, numerical minorities in their own land, have claimed, with varying degrees of success, ownership of resources (primarily land) that were taken from their ancestors when Hawai'i and New Zealand became settler colonies. Fiji, which gained independence from Britain in 1970, has been rocked since 1987 by a series of coups triggered by ethnic conflicts between ethnic Fijians, who maintain ownership of key resources like land, and the descendants of immigrants from South Asia that the British colonial administration in 1879–1920 brought as indentured workers and later as free immigrants. By the late 1960s, Fiji Indians had become numerically dominant but, since the coups and the ethnic violence that accompanied them, many have emigrated to New Zealand, Australia, Canada, and the United States. These varied historical connections, as well as the different configurations in which domination, resistance, and everything in between are embedded, have contributed to the sociopolitical diversity of both regions. Standard reference works on the history of the Pacific Islands, including Polynesia and Micronesia, are Denoon (1997) and Lal and Fortune (2000).

Polynesia and Micronesia in the Global Age

The states and territories of Polynesia and Micronesia include some of the tiniest political entities of the world, such as Tuvalu (12 000 inhabitants, 26 km^2), with few viable economic resources. At the dawn of the twenty-first century, they have been particularly affected by economic problems. The dearth of natural resources in the two regions stands in sharp contrast with some island groups of Melanesia, where minerals and timber have generated substantial wealth for at least some segments of society. In post–World War II years, Nauru stood out as the exception, with one of the highest per capita incomes

in the world thanks to decades of phosphate mining, although extensive financial mismanagement since the end of mining in 2006 have radically altered this situation.

At the same time, capitalism and its institutions have become increasingly determinative, sidelining although not entirely obliterating traditional economies based on reciprocity. Similarly, global forces, in the form of increased population mobility and neoliberal policies enacted by such global entities as the World Trade Organization, are radically altering the social, cultural, and economic landscape in Polynesian and Micronesian societies. The region's economies (be it that of states or that of families) are experiencing increasing difficulties maintaining themselves simply with labor emigration, the remittances that emigrants generates, and a reliance on the continuation of foreign aid from wealthy donor nations, all of which are deeply vulnerable to the vagaries of global economies.

Some states of the region have experimented with what can be described as 'postmodern.' Some states of the region have experimented with what can be described as economic ventures. Polynesian and Micronesian microstates have been particularly proactive in these endeavors. Tuvalu, for example, has invested considerable energy in developing 'resources of jurisdiction,' that is, resources that only exist because of its status as a state. It began with the issuing of increasing quantities of postage stamps aimed at collectors. When philately waned (and the British company contracted to produce the postage stamps was found to be defrauding the government), Tuvalu persuaded Western donor nations to contribute to a trust fund instead of providing direct economic aid. Besides collecting license fees from foreign ships fishing within its 200-mile exclusive economic zone (totaling 600 000 square miles), the country also leased out its telephone country code to international corporate interests, although the Church of Tuvalu pressured the government to end the lease when it found out that the code was used mainly for phone-sex services. Most spectacular is the lease to a Canadian dot-com corporation of the Internet suffix, which fortuitously happens to be '.tv' (thus homophonous with 'television') and is now ubiquitous on the Internet.

Other ventures of the kind, which frequently come with serious social and political drawbacks, have included the sale of nonresidence passports to wealthy stateless foreigners (Tonga), offshore banking (Cook Islands), the sale of flags of convenience to shipping companies (Marshall Islands), the management of detention centers for asylum seekers to Australia (Nauru), and the establishment of offshore factories employing migrant workers (Mariana Islands). More traditional forms of economic development have included the attempt to transform the emigration of low-level unskilled labor into the export of professional labor, such as trained seamen, soldiers, and, most spectacularly, professional athletes. Rugby players from Fiji, Tonga, and Samoa have acquired visibility on the global circuit of athlete mobility, and Samoans who can legally migrate to the United States are overrepresented in American football. Significant numbers of (primarily indigenous) Fijians are recruited in the British armed forces.

These economic ventures, over which island states exert various levels of control, as well as the transnationalization of island populations, have had a considerable impact on the everyday lives of islanders, both materially and culturally. Today, many inhabitants of societies that are the dispersal centers of diasporas lead lives that refer at once to a local and a global context, generating a 'bifocality' of social life that aligns these societies with other diasporic societies of the world (Besnier, 2011). At the same time, island countries have become not only the departure point of labor migration but also its destination, particularly for labor migrants from the People's Republic of China. One manifestation of these complicated dynamics is the emergence, since the last decade of the twentieth century, of new globalized forms of charismatic and Pentecostal Christianity that challenge the hegemony of Christian denominations that have become definers of 'tradition' in the last two centuries and link disenfranchised citizens to global forms of belonging.

The profound changes that have accompanied the emergence of modernity have had a negative effect on the health of islanders. In addition to the surge in cancer rates among populations that have been affected by nuclear testing in the Marshall Islands and French Polynesia, noncommunicable diseases have increased dramatically. Nauru is reputed to have the highest rate of type-2 diabetes in the world, with Samoa and Tonga ranking very high as well. Contributing factors are a genetic propensity for obesity, increasingly sedentary lifestyles, and dramatic changes in dietary habits, including the consumption of low-quality fatty imported meats (Gewertz and Errington, 2010).

Finally, global warming, perhaps the most complex manifestation of the global condition, is poised to affect the region in a particularly dramatic fashion. Polynesia and Micronesia include several political entities that are in danger of complete disappearance within a few decades unless the industrial powers of the world implement radical policies. These include Tuvalu, Tokelau, Kiribati, and the Marshall Islands (as well as, elsewhere in the world, the Maldives and several Caribbean nations), all of which consist of low-lying atolls that are immediately threatened by rising sea levels. Of course, like all disasters and impending disasters, the predicaments faced by these countries and their peoples are as much an ecological phenomenon as a matter of discursive representation. Some politicians and citizens of these countries, for example, have argued that providing health care, adequate transportation, and unimpeded access to labor markets are more pressing priorities than global warming. Clearly, the future of the region is the object of multiple positions of a wide variety of global issues that will, one hopes, take into account the local dynamics of ordinary people's daily lives.

Oil Age: Energy in Transition

Colin J Campbell, Cork, Ireland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The Oil Age opened about 150 years ago and provided an abundant supply of cheap energy that fueled the world's economy, allowing the population to expand sevenfold. But oil and gas are finite resources that were formed in the geological past under processes that are now well understood. It means that they are subject to depletion: in other word's, for every gallon used, one less remains.

Analyzing the status of depletion is difficult because of confusion over the different categories of oil and gas, each having its own endowment, costs, and characteristics. Public information on discovery and reserves is also very unreliable. The skills of a detective are called upon to build a realistic model but a sound picture of the general situation begins to emerge. It shows that we are now about half way through the Oil Age, facing a very difficult transition from expansion to contraction with far-reaching social, economic, and political consequences.

Background

The planet, whose surface is heated by the sun, has had a long geological history spanning billions of years, and has seen many changes ranging from ice ages to epochs of global warming. The continents have broken apart and collided on the back of deep-seated convection currents in the Earth's crust. There have also been epochs of intense volcanic activity putting out massive lava flows and ash clouds, which have changed the composition of both the atmosphere and the oceans. Mountains were uplifted as continents collided, exposing rocks that were subject to erosion, the proceeds of which slipped downward under the forces of gravity to be deposited as gravels, sands, and clays in lowlands, lakes, and seas. Limestone and salt were also deposited under special conditions.

Chemical reactions over 500 million years ago led to early forms of life in lakes and seas, and the remains were preserved as fossils. Some, including, for example, the limpet (or *Patella* to give it its scientific name), have remained little changed, but other species evolved and proliferated when they found a niche that suited them only to die out when that closed from natural causes.

Homo sapiens arrived about 200 000 years ago followed by what could be described as *Modern Man* appearing about 12 000 years ago. People living in any particular chapter of subsequent history naturally assumed that it was the norm and expected it to continue, but history shows that there have often been radical changes, sometimes at short notice.

The Origin of Petroleum

Lough Hyne in SW Ireland is a lake with a narrow channel leading to the sea. It supports a rich fauna and flora, but in the summer, the surface waters warm up and circulation ceases with the result that the depths become stagnant, being deprived of oxygen. As a result its organic life dies. This is a present-day small example of the conditions responsible for the formation of petroleum. In fact, much of the world's oil was formed in two epochs of global warming 90 and 150 million years ago. Algae proliferated in the warm sunlit waters of lakes and restricted seaways in rifts that formed where the continents pulled apart. The organic remains sank to the stagnant depth to be duly buried by sands and clays washed in from the adjoining continents. The organic material was subject to chemical reactions becoming what are known as *kerogens*, some being oil prone and others gas prone. When buried to a depth of about 2000 m, they were heated enough to be converted into petroleum. If buried too deeply into zones of high temperature, the oil broke down into gas. In some cases, subsidence allowed the sea to break into the stagnant lakes and become subject to evaporation leading to the deposition of salt, which formed an excellent seal, preventing the escape of underlying petroleum.

Once formed in so-called source rocks, the oil and gas began to migrate upward to zones of lesser pressure, given that there was enough permeability, partly in the form of fractures, to allow movement. Some escaped at the surface to be weathered and degraded, with the tar sands of Canada being a well-known example. But, in some cases it was trapped in a reservoir of porous rocks at the top of domelike geological structures, known as anticlines. Other traps were formed by faults and where the reservoir pinched out. Such features form objectives for oil exploration. It did not take long for the early explorers to realize that finding an oil field depended on locating a place where the geological conditions of source, trap, reservoir, and seal came together, with timing being an additional important factor. There are many uncertainties, and the geological interpretation requires testing by an exploration borehole, known as a *New Field Wildcat*.

Petroleum Development

Oil and gas have been known from surface seepages since the earliest days, probably being responsible for the biblical burning bush. Commercial development began in the Nineteenth Century with an early mile stone being at Pichelbronn in eastern France where a heavy oil deposit was exploited with shallow wells in 1830. It was followed by other

developments in Romania and on the shores of the Caspian, with an important turning point being the discovery of oil in Pennsylvania in 1859.

At first, the explorers mapped the rocks exposed at the surface, using no more than a hammer, a hand lens, and a notebook, and succeeded in finding many of the major onshore productive provinces. Later came geophysical techniques whereby energy was released from an explosion or other source, and recorders measured the time taken for the echoes to return from rock surfaces far underground, which allowed the geology at depth to be mapped in detail. In recent years, computing power has added ever greater sophistication allowing even the smallest and most subtle prospects to be identified. Geochemistry has also provided a critical insight into where the oil and gas were formed.

As the onshore possibilities dwindled, the industry turned its attention offshore finding extensions of known provinces as well as entirely new ones. This involved the development of special geophysical and drilling equipment. The turning point came with the semisubmersible rig mounted on pontoons floating in stable conditions below the wave base. As the easier possibilities were exhausted, exploration extended into deeper waters, which called for ever more sophisticated technology but faced the occasional serious accident.

The drilling process is indeed complex and calls for a brief description. A drilling bit, even impregnated with diamonds to cut the rocks, is attached to a rotating pipe and drills an initial hole with a wide diameter of as much as 30 inches. The hole is progressively cased with steel pipe, which is cemented into the adjoining rocks, before drilling resumes in progressively narrower holes. A circulating heavy mud, impregnated with barytes, is pumped into the borehole to hold back the pressure from any oil or gas encountered, lubricate the bit, and bring the rock cuttings to the surface, where they are examined to reveal more of the geology. Such boreholes are normally drilled to depths of about 10 000 feet, although in some cases much deeper. They are duly logged by electronic devices to indicate the nature of the rocks penetrated and identify any oil- or gas-bearing zones. If such zones are found, the casing has to be perforated to allow the oil or gas to flow into the well. The borehole starts vertical but can be deviated at depth to run parallel with the strata and thereby put itself into contact with more productive rock. In some cases, an explosive charge was released in the well to fracture the reservoir making it more productive, and that has been followed in recent years by so-called fracking, whereby liquids and chemicals at high pressure are pumped into the rock to increase its permeability.

Once a find was made, attention turned to optimizing the development. This involved drilling appraisal wells to delineate the precise size and nature of the find before investing in the closely spaced development wells to produce it. The infrastructure, including pipelines, had to be planned and constructed at great expense, especially offshore. It was normal and very reasonable to make conservative estimates of the size of the field to minimize the risks to investment, which led to so-called *reserve growth* over the life of the field. The high oil prices of recent years have allowed ever smaller fields to be put on production and have also extended the lives of existing fields, especially offshore. But ironically, these additions leave less for the future.

Control of the Industry and Oil Price

The Standard Oil Company took a dominant early position in the US oil industry, starting primarily as a marketer and refiner before moving progressively into exploration and development, but its power was broken by antitrust legislation in 1911. Even so, three of its daughters, Exxon, Mobil, and Chevron, grew to become major oil companies in their own right, being joined by Texaco and Gulf, following the major discoveries in Texas in the 1930s, and Shell and British Petroleum (BP) in Europe. Together these companies, known as the *Seven Sisters*, controlled the world's supply. They even had a secret meeting in Achnacarry Castle in Scotland in 1928 to regulate production between themselves to support price.

Governments also began to take a role. The US Government moved in the 1930s to support price by limiting production to a certain number of days a month in a policy administered by the Texas Railroad Commission. Communist Russia nationalized its oil industry in 1928, and Mexico followed this example ten years later.

In most countries, mineral rights are owned by the Government that leases them out to oil companies as concessions lasting a set number of years and subject to drilling obligations. But the United States is an exception with the mineral rights belonging to the landowner. The oil fields became important financial assets, leading the Stock Market to impose strict rules on what could be reported as reserves, while smiling on under-reporting as commercial prudence. So-called *Proved Producing Reserves* represented the expected future production from producing wells, while *Proved Undeveloped Reserves* referred to that coming from low-risk infill wells between the existing ones before they had been drilled. *Probable* and *Possible Reserves* were also recognized but had little financial significance. A more sophisticated classification, known as the *Petroleum Resource Management System*, has been adopted in recent years.

In 1960 came the formation of OPEC (*The Organisation of Petroleum Exporting Countries*), which followed the example of the Texas Railroad Commission by limiting the production of its members to support price, the quota being based in part on their reported reserves. But it ran into difficulties when prices fell in the 1980s following the opening of the North Sea and other new offshore areas. In 1984, Kuwait was reporting reserves of 64 Gb (billion barrels) consistent with the long prior trend, but in the following year increased its report to 90 Gb although nothing particular had changed in the oil fields. Possibly, it started reporting *Original* rather than *Remaining* Reserves. Its motive presumably was to secure increased revenue from its resulting higher OPEC quota. Two years later, it announced a possibly genuine small increase to 92 Gb, but this proved too much for its rival OPEC members. Abu Dhabi decided to match Kuwait exactly at 92 Gb (up from 31 Gb); Iran went one better at 93 (up from 49 Gb); and Iraq capped both at a rounded 100 Gb (up from 47 Gb). Venezuela for its part jumped from 25 to 56 Gb but did so by including its heavy *nonconventional* oil that had not previously been counted for quota purposes. Saudi Arabia could not match Kuwait because it was already reporting more but in 1990 announced a massive increase from 179 to 258 Gb to hold its lead. The numbers suggest that Kuwait may have changed to report Original rather than Remaining Reserves, namely by not deducting past production.

The major companies naturally needed to track discovery and the size of reserves around the world in order to plan their investments. In earlier years they provided informal genuine information to Petroconsultants in Geneva, but it was sold on the death of its owner.

There are now several public sources of data on reserves including annual assessments by the Oil & Gas Journal and the BP Statistical Review, which carries a significant footnote to the effect that its published numbers do not reflect the company's own knowledge. The Energy Information Agency, an arm of the US Government, also publishes comprehensive data. There are in addition many web sites providing official assessments by country. These datasets commonly contain different information on reserves, and some show unchanged estimates year on year despite the utterly implausible implication that new discovery and/or *reserve growth* exactly matched the intervening production. There are in addition two industry datasets which are very costly and subject to strict confidentiality, such that they cannot be used for published analyses.

The challenge of determining accurate reserve data has become ever more difficult with the proliferation of small speculative companies and the increasing role of State entities, reluctant to release confidential information. Despite these difficulties, a reasonable approximation of future production by country and region can be made as summarized below.

The Status of Depletion

The first step in studying the depletion profile is to clearly identify the different categories of oil and gas of which there is no standard classification, a cause of further confusion. It is therefore useful to define and identify the following:

1. *Regular Conventional Oil and Gas*: a liquid, known as *condensate*, which naturally condenses from gas, may be treated together with *Regular Conventional Oil*.
2. *Nonconventional Oil and Gas*: made up of the following components:
   a. *heavy oils*: with a density greater than 17.5° API, including bitumen;
   b. *oil shale*: oil that can be produced by heating immature source rocks;
   c. *tight oil and gas* (*also called shale oil and gas*): as derived from rocks lacking adequate natural porosity and permeability that can yield production when artificially fractured;
   d. *deepwater oil and gas*: in water depths greater than 500 m.
   e. polar oil and gas;
   f. natural gas liquids from gas plants;
   g. *other nonconventional gases*: coalbed methane, hydrates, etc.

Regular Conventional, which was relatively easy and cheap to produce, has dominated all past production and is likely to continue to do so for many years to come, although *nonconventional* sources are being increasingly tapped.

It has also been found useful to treat everything in terms of production to the end of the Century to avoid having to worry about some insignificant tail end. Subtracting past production from the estimated total gives future production, a certain percentage being deemed to come from known fields, namely *reserves*, with the balance being yet-to-find.

There are 64 significant oil-producing countries to be evaluated. The study involves many iterative steps, starting with the input of past production, discovery, and the number of exploration boreholes drilled per year. The larger fields were usually found first for obvious reasons, and plotting cumulative past discovery against exploration boreholes, the so-called *creaming curve*, can be extrapolated to give an indication of the total, as illustrated by the example of Norway below. Another method is to analyze the distribution of field size against rank with the *parabolic fractal* (Laherrère, 1996). The indicated total is then evaluated and adjusted if necessary taking into account various relationships, including the status of depletion, with the peak of production normally coming approximately at the midpoint of depletion. Some 50 countries are now producing less than at some date in the past, many being long into decline.

The following graphs summarize the conclusions. The first shows that discovery peaked in the 1960s, as confirmed by an Exxon executive (Longwell, 2002), such that by 1981 we were producing more than what was being found in new fields. The second plots the depletion profile of all categories of oil and gas. *Regular Conventional Oil* peaked in 2005, but all categories have followed a plateau over the past few years which may extend further. One year will obviously deliver a high point on that plateau, such being tentatively identified as coming in 2015. A debate rages as to the precise date but misses the point when what matters is the vision of the long decline on the other side of it. The longer the plateau, the steeper will be the subsequent decline. *Regular Conventional Gas* is expected to peak around 2015. More details are given in the following table and in the Atlas of Oil and Gas Depletion (Campbell, 2013).

The Wider Significance in a Historical Context

The species *H. sapiens* arrived about 200 000 years ago, and settled agriculture followed about 12 000 years ago. Crops had to be stored between harvests and those controlling the storehouse had to keep accounts of how much was received and returned to the farmers. They were also able to give preference to the privileged members of their societies and charge interest for the loan of food after a bad harvest. In other words, they laid the foundations for banking.

We may imagine that at some point someone found a nugget of gold in a riverbed and showed it to a neighbor, who liked it even more, perhaps offering to exchange it for a sack of corn. It came to facilitate barter, laying the foundations for trade, and silver had a similar role.

Stone Age Man had used flints before people turned to bronze, iron, and steel for better tools and weapons. These

Notes: DR refers to depletion rate (annual as a percent of future). Dep. stands for depleted. Eurasia is the former Communist bloc and China. N. America is USA & Canada. ME Gulf is Iran, Iraq, Kuwait, Neutral Zone, Saudi Arabia, and United Arab Emirates. Only major producing countries are included in each region, with the rest in Other The World Totals include a rounding of −19 Gb for oil and +271 Tcf for gas.

minerals were dug from surface outcrops before the pits were deepened into mines, but they flooded on hitting the water table. For fuel, people relied on wood and charcoal before turning to coal, also dug from pits that were deepened into mines.

Trade and industry developed over time, and the Eighteenth Century saw the birth of the so-called *Industrial Revolution* which led to the rapid increase in the demand for coal and minerals. Draining the mines led to a remarkable technological development: the hand pump evolved into the steam pump which in turn led to the steam engine. It greatly facilitated transport with the construction of railways and steam-driven ships that further encouraged trade and industry. The next important step came when a way was found to insert the fuel directly into the cylinder, giving the *Internal Combustion Engine* which was much more efficient. At first, it used benzene distilled from coal before turning to petroleum refined from crude oil. The first automobiles took to the road around 1880 and the first tractor ploughed its furrow in 1907 leading to the rapid expansion of agriculture to feed the expanding population, which then stood at about 1.5 billion.

This new prolific source of cheap energy changed the world in radical ways allowing the population to expand sevenfold in parallel. But it was not plain sailing as trade prompted the growth of empires which in turn led to major conflicts between rival powers. Whereas, in earlier years, short battles had been practical ways of settling disputes, the advances in weapons technology and the provision of railways to keep the front supplied with munitions and reinforcements transformed the First World War of 1914–18 into an appalling exercise of attrition on the killing fields of Flanders. Wars were expensive exercises largely funded by debt, which had to be settled after the war, leading in turn to social and political tensions. The Second World War of 1939–45 was essentially an extension of the First.

The British Empire was extinguished by the war, and the United States became the world's premier power with the dollar being adopted as a world trading currency. The so-called Cold War followed allowing the United States to increase its dominion around the world with military bases which indirectly strengthened its financial power and thereby trade. The dollar was at first backed by gold, but that practice was abandoned in 1971, allowing the financial institutions to adopt ever more complex and speculative manipulations, with debt itself even becoming a tradable commodity. The US industrial base, however, began to decline as its companies increasingly moved overseas for cheaper labor.

But whatever the conflicts, it was generally a successful chapter in history allowing the so-called standard of living for many people to grow as trade expanded. Women no longer saw their prime role as wives and mothers but developed careers and played an important part in the new consumeristic society. Radio, television, and, later, the Internet had a huge impact giving people a wider view of the world, subjecting them to the pressure of advertising.

The economic prosperity of this chapter of history was fueled by cheap oil-based energy allowing the roads to become choked with traffic while airliners carrying holiday-makers to distant beaches left trails across the skies. It marked the *First Half* of the *Oil Age* with production rising from about 4 million barrels a day in 1930 to pass 10 million in 1950 and 80 million in 2004 (a barrel contains 42 gallons). Oil prices were relatively stable over the last Century averaging $25 a barrel (quoted in terms of 2011 dollars), although there were surges to $53 in 1974, when OPEC countries restricted supply to counter US support for Israel, and to $101 in 1980 on fears of further interruptions following the fall of the Shah of Iran.

But the depletion of oil, which is a finite resource formed in the geological past, as described above, began to influence prices as the present Century opened. The major companies began to find it easier to acquire reserves than to find them by exploration, such that the *Seven Sisters* were reduced to four by merger. Most production came from *Regular Conventional* sources and prices reached to $63 in 2005 when its natural peak of production was passed. Traders spotted the rising trend and bought contracts on the Future's Market which led prices to soar to almost $150 by mid-2008. The scale of speculation is illustrated by the fact that contracts on the Future's Market exceeded actual production by factors of 10 to 30 (Tolub and Erb, 2010). The traders, realizing that the high prices would cause recession dampening demand, then started selling *short* on the market, while the industry for its part began draining its storage tanks to benefit from the high prices while they lasted. Prices accordingly fell back to $64 in 2009. Prices anomalously fell again in late 2014 to around $80, due, it is said to action by Saudi Arabia but it is too soon to be sure. The downturn is likely to be short-lived.

Governments, following outdated economic principles, reacted to the recession by printing yet more money out of thin air in the hope of stimulating consumerism to restore past prosperity. They met with a brief success such that the demand for oil again rose, and oil prices passed $111 in 2011, suggesting that recession is set to resume.

The industry reacted to the peak of *Regular Conventional Oil* in 2005 by turning more attention to *nonconventional* sources which are both more expensive and slower to extract. Wells were drilled to great depths in ever deeper waters, especially in the Gulf of Mexico and off Brazil and West Africa. In the United States, great attention has recently turned to so-called fracking, whereby expensive and short-lived highly deviated wells can extract limited production from rocks lacking adequate natural porosity and permeability to form a reservoir. The resource in the ground is enormous and unquantifiable, but extraction is slow and very costly, also facing environmental objections. No one would turn to this supply if there was adequate *Regular Conventional Oil* left.

The European Union was formed out of 27 countries, supporting a population of 550 million, to provide a common market and end the cause of conflicts that had led to the two world wars. Many of these countries adopted a common currency, the Euro, but it too has run into financial difficulties. In earlier years, Europe had led the world in terms of coal mining, which provided the energy for its rapid industrialization, but that production has long been in decline, Britain's production having peaked in 1914. France in particular turned to nuclear energy as a response. But the discovery of oil and gas in the North Sea led to a surge of new energy, although it too is subject to depletion with oil production passing a peak in 2000 and gas 4 years later. The high level of technical expertise and the stable operating conditions ironically accelerated depletion such that the *Depletion Rate* (Annual as a percentage of Future) stands at a relatively high level at 5% for oil and slightly more

for gas. It means that oil and gas production will have fallen to about half their present levels in about 10 years' time.

As countries begin to appreciate the depletion of their oil and gas, they are likely to restrict exports to conserve as much as possible for their own future needs. It makes eminent national sense although offending the principles of globalism whereby the resources of any country belong to the highest bidder. Argentina has already taken a lead in this direction, and King Abdullah of Saudi Arabia has perceptively said that he wishes to leave as much wealth as possible in the ground for his grandsons.

Every country and region faces comparable changes, such that the world production of *Regular Conventional Oil* and *Gas* will have fallen to half their present levels by about 2040 and 2065 respectively, suggesting that by the middle of the Century the world will be able to support no more than about half its present population in its present way of life.

The transition imposed by Peak Oil and Gas threatens to be a time of great tension as indeed has already been observed in the form of riots and revolutions around the world. Food prices have increased fivefold reflecting the rising cost of oil, agriculture having been described as a process which turns oil into food (Brown, 2012). The so-called *Arab Spring* affecting countries in North Africa and the Middle East was particularly severe. People became resentful and blamed their governments for their changed circumstances. Some of these countries are important oil producers and may be subject to foreign military intervention, as was the case in Libya.

The transition has also particularly affected the financial system. The banks had been lending more than they had on deposit confident that *Tomorrow's Economic Growth* was collateral for *To-day's Debt*. But growth is no longer possible without cheap oil-based energy, explaining why debt went bad. The United States Empire is essentially a financial one, and it faces a particularly difficult transition. It built up a substantial military presence around the world during the Cold War which helped ensure that countries used the dollar for trade and held their reserves in that currency. The North Atlantic Treaty Organization (NATO) was established as a defensive pact whereby it would go to the support of any of its members under attack, but the rules were progressively modified allowing intervention if its *vital interests* were at risk, oil supply being certainly such. Indeed, President Bush justified the invasion of Iraq with the words – *our energy supply was at risk*. The fall of the Soviets led to the opening of the oil-rich Caspian, which was once thought might rival the Middle East, and the United States attacked Afghanistan lying on a proposed export pipeline route. Iran, another major oil producer, has been under threat, having been subject to financial sanctions by the United States and some of its European supporters.

But it is not a hopeless situation as people and their governments can react in positive ways to meet the changed circumstances, once they come to understand that the depletion of the critical energy supply that supports their current style of life is imposed by natural depletion. It seems likely that there will be a reversion to localization as people again come to rely on whatever their particular region can support. Scotland is already considering seceding from the United Kingdom, as many as 45% of the voters agreeing in a recent referendum, as does the province of Catalonia from Spain. The various states making up the United States, which already have considerable political power, may also move to reduce the authority of the Federal Government, even if they do not formally secede from the Union.

It is not difficult to think of specific policies that would help reduce energy demand:

1. Adopt the *Oil Depletion Protocol*: Already the Portuguese Parliament has passed a resolution urging its Government to adopt a policy for cutting consumption to match world depletion rate (*Annual* as a percentage of estimated *Future* production), and a new political party in the Spanish province of Galicia has adopted it as part of its platform (Partido de la Terra). Depletion is currently running at no more than about 2.5% a year for *Regular Conventional Oil* and less than 1% for all categories. Cutting demand by such small amounts should be readily attainable. Such policies would also hold prices down helping the poorer nations and reduce the tensions.
2. Progressively disallow energy costs as a charge against corporate taxable income, which is a form of hidden subsidy. Management, facing these costs head-on, would likely react by paying more attention to energy efficiency, for which there is much scope.
3. Install smart meters so that households may be more aware of their electricity consumption, much of which is generated from gas, and impose new tariffs whereby the cost per unit rises with increasing consumption. France already has meters with a red light that comes on at periods of peak demand increasing the tariff at those times significantly.
4. Encourage car sharing whereby people come to give lifts, sharing the cost of the fuel, which itself might be subject to an affordable tradable ration, providing for minimal essential needs to people in different circumstances.
5. Encourage the development of energy from tides, waves, and wind, as well as that from solar and geothermal sources. Home-owned windmills and solar-power facilities can make households largely self-sufficient, even selling a surplus back to the grid. Anaerobic digestion, by which urban and agricultural organic waste is used to generate methane, can also contribute.
6. Encourage a new regionalism with local currencies, managed responsibly, whereby people may become less oil-dependent and again rely on what their particular region can support. This might prompt a new more positive democracy whereby the leaders are better linked to the people they represent, being freed from hidden financial and other pressures.
7. Above all, take measures to reduce the world population.

In conclusion, it may be said that the evolution of life on Earth has seen many changes. *H. sapiens* does not necessarily face an early extinction, but *Petroleum Man* will be about gone by the end of the Century. The challenges for survival are real but can be met once the issues at stake are better appreciated. Indeed, it is promising that the subject is now attracting much interest with academic research, notably by the UGES Research Group at Uppsala University in Sweden established by Prof. Aleklett, who also heads the Association for the Study of Peak Oil and Gas ('ASPO') with associates in more than 30 countries. But the challenges of adapting to the changes resulting from the radical fall in the principal energy source supplying the modern world are daunting.

Old Age and Centenarians: The Human 'Warranty Period'

Bruce A Carnes, College of Medicine, The University of Oklahoma Health Sciences Center, Oklahoma City, OK, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

More humans are surviving to older ages than ever before. The age structure of our species is shifting from young to old, a phenomenon referred to as population aging. It is global in nature, uniquely human, and has become one of the greatest challenges ever encountered by our species. The basis for this assertion is that biological function (homeostasis) declines with advancing age and at the same time pathologies, frailty, and disability increase. Given these biological realities, this article examines whether humans have a warranty period, when do we grow old, and what are the odds of becoming a centenarian.

Humans are the only species who live most of their lives knowing they will eventually die. This knowledge has made duration of life a topic of discussion and conjecture throughout recorded history. Terminology related to duration of life has proliferated over the centuries. However, without a conceptual framework, this terminology has created confusion and misunderstanding across scientific disciplines as well as in the general public. In an age of population aging, scientific clarity is an essential precursor to the creation and implementation of effective social policy (*see* Population Aging: Economic and Social Consequences). An interdisciplinary framework for clarifying this terminology will be provided. The article will also examine commonly asked questions about age, aging, and longevity. For example: At what age do we become old? Can everyone become a centenarian? How long can humans live? We will examine whether these are even the right questions to ask. Identifying appropriate questions and answers is especially important now because the individual and societal consequences of extended longevity are threatening the social fabric of nations, communities, and families around the world.

Terminology and Premise

The terminology discussion begins with the most fundamental term, life span (Carnes, 2011). *Life span* is just what it sounds like; it is a term that describes the observed length of a person's life. It is an 'obituary' (birth to death) concept that replaces the older and more cumbersome *duration of life* terminology. *Longevity* is also defined as length of life, but dictionaries associate this term with a long duration of life. The latter distinction is important because genetic analyses of longevity suggest that it is heritable (i.e., influenced by genes). Life span lacks this genetic distinction (*see* Lifespan Development, Theory of).

Although seemingly straightforward, life span remains a fuzzy concept that creates considerable confusion in the field of gerontology. The basis for this confusion begins with the premise that nearly every death is premature. In other words, most deaths are avoidable, and human history can be viewed as a continuous search for ways to avoid avoidable mortality. By implication, everyone has a *potential life span* that under better circumstances (improved environment, better medical care) is within their grasp. This ability to pursue our own potential life span is personally empowering, further distinguishes humans from other species, and motivates the interdisciplinary pursuit of social policies aimed at increasing healthy life span.

The time between observed and potential life span is reclaimable without modifying our biology. Dentistry, medicine, public health, and other related pursuits are creations of human ingenuity intentionally designed to improve health and *manufacture survival time* (Olshansky et al., 1998). The clearest evidence of success for this remarkable Lamarckian (technological) endeavor is the rapid climb in life expectancy that has occurred over the last century. Our species has bypassed the rules of evolution through adaptations to environmental challenges that were achieved via culture and technology rather than biology.

The Great Unnatural Experiment

Peter Medawar (1952), Nobel laureate and one of the founding fathers of gerontology, declared that senility (or what we call senescence or aging today) is "an artifact of domestication; that is, something revealed and made manifest only by the most unnatural experiment of prolonging an animal's life by sheltering it from the hazards of its ordinary existence." Medawar saw the future long before the pace of manufacturing survival time had accelerated or the term population aging even existed or was an issue of societal concern. He understood that the future would be a world that bears almost no resemblance to the world from which our species and our biology emerged.

Human ingenuity not only created the opportunity for many to achieve or approximate their potential life span, it may have reached a level of technological sophistication that allows some people to exceed their potential life span as well. People who would have died at an earlier age in the past are routinely saved today. Historically, the older segments of human populations were populated by the robust survivors of an unforgiving gauntlet of death (demographic selection). Today, the older segments of our populations are far more diverse in a health sense than in the past and will be even more diverse as new ways are found to save lives in the future. Lowering the barriers to extended survival and the biomedical and social consequences that arise from it are already being felt around

the world (*see* Retirement and Encore Adulthood: The New Later Life Course).

Asking the Right Questions

For most of human history, life expectancy at birth for humans has been below 50 years. However, since 1900, life expectancy has climbed dramatically. This demographic trend has led both the public and the scientific community to ask: How long can humans live? The first reaction to this question is that it has no single answer because humans are not genetic clones. Madame Jeanne Calment, the longevity world record holder, died in 1997 at the age of 122 years and 164 days. As the cumulative number of humans ever born continues to increase, the odds will increase that her record will be broken some day. However, for every longevity record holder, there will be millions of fetuses that die before birth and billions of people who will die at double digit ages.

The rareness of people who achieve extreme longevity makes them a curiosity. Based on the 2006 U.S. period mortality table, the probability of surviving from birth to age 100 is 2.5% for females and 1.1% for males (NBER, 2013). However, demographers point out that life expectancy has increased at a pace of 1/4 year per year over the last two centuries (Burger et al., 2012). If this trend continues in high life expectancy countries, then demographic models predict that 50% of the babies born since the year 2000 will live to celebrate their 100th birthday (Christensen et al., 2009). If this prediction of extended survival becomes a demographic reality, then ways to extend healthy life span become essential in order to avoid trading off longer life for progressively worsening health (Olshansky et al., 1991). From a biodemographic perspective, biology trumps demography because it is more proximate to the underlying causes of both longevity and aging. As such, asking how long humans must live is a more relevant scientific question than asking how long can humans live. The former has a biological answer but the latter does not.

Warranties and Their Expiration Dates

We are all familiar with the expiration date of warranties; we look for them when we buy eggs or milk at the store and when we purchase cars. Everything created, including the human body, has an implied warranty period. As such, it is scientifically reasonable to search for ways to estimate an expiration date for the biological warranty period of humans. In order to avoid falling into conceptual traps, a few comments are required. The first of these is that a biological warranty period has nothing to do with life span limits. As mentioned earlier, life span limits just like Olympic records are invariably broken and exist only in a probabilistic sense; that is, the probability of surviving to the longevity record diminishes as the record is progressively surpassed. The second clarification about warranty periods is that they are not a death sentence. Eggs can be eaten beyond the expiration date, and cars do not fall apart on the day their warranty expires. Instead, the warranty period establishes a boundary between a period of normal operation characterized by health and vigor and a period of extended operation, where maintaining health and vigor becomes progressively harder to achieve. In a world of population aging, identifying the age of this transition is exceedingly relevant to the development of realistic policies associated with retirement, medical care, elder health, and social justice.

Medical and social science researchers partition the human life course into childhood, adulthood, and a postreproductive period (*see* Motivation: Life Course and Sociological Perspectives). This development-based framework enables them to organize their medical training and practice into pediatrics, internal medicine, and geriatric medicine and to identify the unique medical and social challenges that occur within these phases of the life course. For social scientists, it allows them to examine the unique life phases related to reproduction, mating, and employment. A warranty period is different; it provides an answer to the question: "How long must humans live?" The logic goes as follows. Every living thing eventually dies. Given this biological reality, life on the earth must have found a solution to the inevitability of death and it did – reproduction. Thus, the answer to the question is "humans must live long enough to replace themselves," or as a biologist would say, they must live long enough to achieve Darwinian success.

Multicellular organisms are not born mature; it takes time for them to reach a level of developmental maturity that makes reproduction biologically possible. As such, a highly orchestrated (i.e., genetically programmed) sequence of developmental milestones must be successfully navigated: conception, growth and development, maturation, reproduction, nurturing, parenting, postreproductive parenting, and in humans, grandparenting. The window of time needed to accomplish these biological milestones has been called adaptive life span (Gurven and Kaplan, 2007), essential life span (Rattan, 2000), or biological warranty period (Carnes and Witten, 2014). The heritability (attributable to genetics) of generic life span is approximately 15%, but the heritability of longevity (long life) increases as it is progressively lengthened (Gögele et al., 2011). All three concepts (life span, longevity, and warranty period) are measures of time created by varying degrees of biology/genetics (*see* Behavioral Genetics: Psychological Perspectives).

Quantifying the Warranty Period

Quantifying the human warranty period requires associating chronological ages with developmental milestones (*see* Age Structure; Age Stratification). Medawar's unnatural experiment complicates this task by distorting the natural timing of the milestones. The inevitability of death (mortality pressure) essentially defines many of the milestones because it creates a literal race between reproduction and death. Death before reproduction is the ultimate biological failure (*see* Fertility Theory: Theory of Life History Evolution). In nature, organisms must reproduce as early as is physiologically possible. Our distant ancestors as well as extant hunter-gatherers would have to do the same. Thus, on average, sexual maturity is achieved at 16.1 years of age and the first birth occurs at 19.5 years of age in hunter-gatherer societies (Walker et al., 2006).

In developed countries (countries experiencing Medawar's unnatural experiment), age of sexual maturity drops, on average, to 12.5 years, presumably because of easy access to

a surplus of food. Conversely, age of the first birth in developed countries is delayed to 24 years for all women or 26.5 years for educated women. Further, first births beyond age 30 are not unusual. So, women in developed countries are reaching sexual maturity earlier and reproducing later. This shift in reproductive behavior creates a large disparity between age of menarche and the first birth; it is 3.4 years in hunter-gatherer societies and 11.5 or 14 years in developed countries depending on whether you measure it for all women or women who are educated (Piñón, 2002). These disparities between ancestral and modern ages for important biological milestones raise an important question: Was it our biology, our behavior, or both that changed in response to changing environments?

Evolutionary biologists (e.g., Pritchard, 2010) suggest that the pace of global colonization by humans outpaced any credible rate of biological evolution (*see* Lifespan Development: Evolutionary Perspectives). To be sure, genetic change within our species did occur (e.g., lactose, hypoxia, melanin, and sickle cell gene), but recent genomic studies suggest the baseline rate of mutation (evolutionary change) is 50% slower than previously thought (Arsdale, 2012). This finding leads to the conclusion that cultural and technological adaptations are largely responsible for why humans were able to populate the globe so rapidly. In other words, our biology has remained largely unchanged, but our culture and technology has undergone dramatic transformations. To come full circle, this is exactly what Medawar meant with his colorful analogy to an unnatural experiment of prolonging life by creating artificial environments that shelter humans from the mortality risks of natural ecosystems.

If, as argued, human biology has remained largely the same, then hunter-gatherer 'ages' are likely to better reflect our ancestral biology than the same estimates derived from data for modern societies. Human societies sheltered from modernity avoid Medawar's unnatural experiment. Thus, age for maturity, first birth, and menopause are 16, 19, and 45 years, respectively (Piñón, 2002). This scenario also suggests grandparents would have emerged in the late 30s rather than the 50s and 60s observed in developed countries today. Although fertility patterns vary across many dimensions (e.g., geography and time), the vast majority of children ever born are born to mothers younger than 35 (Martinez et al., 2012). This age of cumulative reproduction can be referred to as the effective end of reproduction (EER) as opposed to menopause, the absolute end of reproduction.

Giving birth, however, is the beginning of a journey, not the end of one. Using 35 years as a conservative estimate for the EER, the mother would be 51 years old when her last child reaches the age of independence. Taken together, these milestones imply that the warranty period for humans is approximately 50–55 years (EER + age of independence). This age range may seem too young by today's standards, but it would not seem young 100 000 years ago or even in 1900 when life expectancy in the U.S. was 48.23 and 51.08 years for white males and females, respectively (HMD, 2013).

At What Age Do We Become Old?

Although the age-related physiological consequences of aging are fairly predictable (Shock, 1983), there is significant phenotypic and functional variation among individuals within and between chronological ages (*see* Age Stratification). As such, 'old' is a concept that cannot be uniquely measured or quantified from a biological perspective. Just as there is no specific age when a person is no longer young, there is also no specific age when a person becomes old. Further, identifying a specific chronological age as old is treating a continuous variable as though it is a discrete step-function variable. By general consensus, geriatricians view age 65 as the beginning of the geriatric years and by implication the gateway to old age. Of course, applying labels to segments of a continuum involves creating cut points that by their nature are arbitrary. The question, however, is whether the geriatric classification is reasonable.

The warranty period concept provides context for this question. Old, by definition (Merriam-Webster, 2013), means 'advanced in years or age' as well as 'showing the effects of time or use.' The latter implies that 'old' should be associated with elevated morbidity (frailty, disability) and their mortality risks (Fried et al., 2004). Thus, the chronological ages at which age-specific death rates begin to accelerate should serve as a harbinger of old age.

Parametric survival models provide a way to formally quantify the acceleration of mortality and its implied morbidity. Consider the Gompertz hazard rate (Elandt-Johnson and Johnson, 1980), which can be expressed as $\lambda(t) = \alpha e^{\beta t}$. In the language of physics, the hazard rate is a velocity function. As such, the first derivative of the hazard function measures acceleration and in the case of the Gompertz, it is nothing more than the slope parameter (β) times the hazard rate ($\lambda(t)$). The new function describes the 'acceleration of mortality' that a Gompertz population experiences as it travels along its dying out trajectory on the age axis.

Although demographers typically model all-cause mortality, there are many causes of death that compete for the lives of individuals. William Makeham (1867), an English actuary, recognized this issue and modified the Gompertz function to distinguish accidental deaths (age-independent, extrinsic) from biological deaths (age-dependent, intrinsic). In so doing, he improved the fit of the Gompertz function, created a new field of research now called competing risk theory, and became the father of biodemography. The latter moniker relates to his biologically motivated partition of mortality, which is a methodological characteristic that distinguishes biodemography from demography (Carnes and Olshansky, 1997). His binary cause-of-death partition allowed him to detect mortality dynamics that were otherwise hidden within the all-cause Gompertz pattern of age-specific mortality.

When applied to any mortality data for a developed country, the acceleration of intrinsic mortality will be minimal within the warranty period (Carnes and Witten, 2014). By age 50–55 years, mortality acceleration is approximately four times faster than during the decade of the 40s. However, a fourfold increase of a small acceleration is still a small acceleration. By age 65, mortality acceleration is approximately 12 times higher than what is observed within the warranty period. This level of acceleration is consistent with the geriatric notion of a gateway to old age – mortality risks are elevated, but not yet severe. The acceleration of mortality increases 20-fold by age 70, which would be consistent with 'old.' By age 80, mortality has accelerated by 40- to 50-fold, which would be consistent with Suzman et al. (1992) concept of the 'oldest old.' Although these

labels assigned to segments of a continuous variable may be conceptually useful and mathematically consistent, they must still be viewed as subjective.

There is also an acceleration of extrinsic mortality across the age spectrum, but it only achieves a fourfold increase (relative to within the warranty period) by age 80. In other words, the acceleration of extrinsic mortality is nearly constant. This finding is historically interesting because Makeham himself viewed his partition as distinguishing between age-dependent (intrinsic) and age-independent (extrinsic) causes of death. The minimal acceleration observed in the latter is therefore consistent with Makeham's predictions in 1867.

Can Most of Us Become Centenarians?

This is a frequently discussed issue in gerontology, and schools of thought fall into three general categories. Futurists suggest technology can scientifically engineer negligible senescence (SENS) such that life spans in excess of 1000 years and even immortality are already possible (de Grey, 2002; Kurzweil and Grossman, 2005). Forecasts made by respected demographers have predicted that 50% of every cohort from 2000 onward will survive to age 100 and beyond in developed countries (Christensen et al., 2009). Although biodemographers also forecast continued increases in life expectancies, their more modest longevity predictions (Carnes and Olshansky, 2007) have been described as an example of the pessimistic school of demographic thought (Bongaarts, 2006).

Despite the lack of evidence-based support, the SENS view was included here because this school of thought does have a visible presence within gerontology communities around the world. As mentioned, the demographic view of longevity not only has considerable support, but their methods of analysis and predictions influence agencies like the Social Security Administration when they create hypothetical scenarios in order to assess the impact of demographic stresses on the future solvency of this age-based entitlement program. By way of reminder, the biodemographic perspective is the one used throughout this article (Carnes and Olshansky, 1993).

As in the previous section, the warranty period concept provides a context for examining this extreme longevity question. Recall that ages 50–55 were declared the expiration of the human warranty period, and age 65 was identified as the gateway to old age. From this perspective, the difficulty of maintaining the biological integrity of an organism increases as survival beyond the warranty period increases. There are multiple reasons for this degradation, and they all fall within the rubric that while organisms are not designed to fail, neither are they designed for extended operation. One of the principle reasons for this phenomenon is aging itself, which is defined here as the functional degradation that arises from the "irreparable damage accumulation of biochemical side-reactions" (Yin and Chen, 2005).

An extension of this stochastic view of aging motivates the 'junk theory' of aging (Terman and Brunk, 2006), namely, "normal metabolism is associated with unavoidable mild oxidative stress" that results in "biomolecular damage that cannot be totally repaired or removed by cellular degradative systems." Thus, biochemical side-reactions and oxidative damage create an accumulation of 'irreversibly damaged and functionally defective structures (biological garbage)' that degrade homeodynamic processes and increase the age-specific probability of morbidity and eventual death. On a more evolutionary timescale, this degradation can be viewed as the cost of multicellularity. The mitochondria (cellular organelles), whose increased energy production made multicellular life possible also generate the unintended free radicals that contribute to the accumulating damage initially described in the free radical theory of aging (Harman, 1956).

These biological theories of aging suggest that survival to age 100 and beyond falls far beyond the human warranty period. Demographic evidence supports this conclusion (Carnes et al., 2012). Between 1935 and 2000, the probability of surviving to age 100 (based on U.S. period life tables) increased from 0.22% to 1.8% for females and from 0.09% to 0.49% in males (SSA, 2012). Even in Japan, where female life expectancy at birth is the highest in the world, the probability of surviving to age 100 in the year 2000 was 4.5% (HMD, 2013). These demographic results reveal an important biological reality: the probability of surviving to age 100 is exceedingly low – less than 2% for a female and only one-fourth of that for a male. It is equally important to recognize that biological reality establishes the boundary conditions within which demographic forecasts should or even must fall. Predictions of longevity that fall outside the boundaries of established biological plausibility cannot be justified mathematically; they require an evidence-based biological explanation.

What Makes Extreme Longevity Possible?

Despite poor longevity odds, there must be ways to achieve exceptional longevity, since an estimated 53 000 centenarians and supercentenarians were living in the U.S. in 2010 (Howden and Meyer, 2011). It is probable that every pathway to surviving 100 years requires winning the genetic lottery at birth (Gogele et al., 2011) while also successfully avoiding avoidable (premature) mortality (Perls and Terry, 2003; Willcox et al., 2006). The Forkhead Box O3A gene (FOXO3A) seems to be a genuine longevity gene (Willcox et al., 2008). As age increases, so does the prevalence of FOXO3A – an age pattern of demographic selection that is consistent with a survival advantage for individuals with this genotype.

As with FOXO3A and other longevity genes (Lombard and Miller, 2012) there is no real debate over whether these genes extend survival. In fact, there is good reason for expecting longevity genes to exist because longevity is a prerequisite for achieving the most fundamental task of any organism, reproduction; hence the warranty period and the genes that enable it. When environmental conditions challenge the survival capacity of organisms, the ability to survive one more day or week or month can make the difference between successful reproduction and death before reproduction. As such, the physiological plasticity to survive environmental challenges is an essential component of a broader genetic-based complex of adaptive responses that occur at all levels of biological organization within an organism. In other words, longevity or survival assurance is as much a part of an organism as its anatomy. In fact, biological complexity

theorists would say longevity and adaptation are emergent behaviors (the whole being greater than the sum of parts) of an organism (Carnes et al., 2010).

Living beyond 90 or 100 years, however, is survival that far exceeds expectation. It is an anomaly relative to the survival pattern observed for the vast majority of the population. Raymond Pearl (1946), one of the first biogerontologists, performed a detailed genealogical analysis of human pedigrees to reveal the conditions required for becoming longevous or what we would describe today as achieving extreme longevity. His analysis led him to conclude that in order to become longevous one must "select long-lived parents, and particularly long-lived mothers." However, to be fair to men, more recent analyses suggest that long-lived fathers may be just as important as long-lived mothers in determining the longevity of their offspring (Gavrilov et al., 1998). Of course, we do not pick our parents, but these genealogical findings are consistent with the notion that extreme longevity involves winning a genetic lottery at birth.

Although genetics plays a major role in establishing a warranty period and enabling extreme longevity, the genetic basis of these two phenomena probably differs. A vast majority of people possess the genetic capacity to survive 50–55 years in good health. Surviving 90 years or more in good health is far harder than surviving 50–55 years in good health. Do genes within either or both of these categories influence the biological rate of aging? The jury is out on this question and thus the scientific debates continue (Olshansky et al., 2002).

The disposable soma theory of aging (Kirkwood and Holliday, 1979) is one of the key theoretical foundations of gerontology. It posits that the inevitability of death (mortality pressures) gives reproduction a higher biological priority than maintenance of the soma (body). Hamilton (1966), one of our great evolutionary biologists, implied that the biology of a species is molded by the external mortality pressures acting upon it. This molding can be easily seen at a species level. Mice live short lives and produce large numbers of offspring because nearly everything eats mice. Mortality pressure on humans, however, is much lower, and this enables our species to mature more slowly, reproduce later, and have fewer children. In essence then, there is a trade-off between fertility and longevity. As mentioned, this trade-off is visible at a species level, but what about within species? Do women who become centenarians have fewer children than women who die at typical ages? Research on humans does support a trade-off between fertility and longevity (Westendorp and Kirkwood, 1998; Corbo et al., 2008), but it is also becoming clear that this presumed rule has exceptions (Partridge et al., 2005; Reznick et al., 2000).

Demographic evidence for extreme longevity is dubious for several reasons. The most important reason is that demography studies populations, not individuals. The actuarial rate of aging or the mortality rate doubling time has nothing to do with an individual; they are measures of the speed at which a population dies out. Between 1900 and 2000, life expectancy at birth (sexes combined) in Sweden increased from 58.03 to 79.83 years, a 27.56-year increase (HMD, 2013). Nearly all of that increase can be attributed to saving children from infectious and parasitic disease death and saving mothers from dying during childbirth. In other words, the collective extension of Swedish life spans has little or nothing to do with modifying or quantifying the rate at which Swedes age. This argument is not intended to demean demography; life expectancy is a valuable metric for quantifying population health trends over time. The primary point here is that life spans in the collective can be increased without modifying the biology of humans or the rate or rates of aging.

Closing Thoughts

When viewed through the prism of life on the earth, human biology is just a continuation of an ongoing theme. Out of that mundane status quo came something that could not have been predicted from the past. Virtually every species does something spectacular, but that ability has always had an explainable biological origin. However, no other species in the history of life on the earth has come even close to the ingenuity of hominids and the culture and technology that we have created. Much of that technological innovation has been directed toward progressively isolating ourselves from the mortality risks that have been imposed on us by the environment and microbes (Olshansky et al., 1997). This progressive sheltering from the hazards of ordinary existence is largely responsible for why every generation of humans is setting a new longevity record.

New technologies are being turned inward to reduce the health, disease, and mortality risks arising from bodies built from an imperfect design that uses imperfect building materials and is maintained by imperfect surveillance, maintenance, and repair processes. Despite these design challenges, our technologies have led to unprecedented population growth, unprecedented increases in life expectancy, and unprecedented survival to older ages. Our innovations have produced many blessings, but in doing so have created many new challenges. Fewer of us succumb to microbes, but one in every three seniors now dies with Alzheimer's or other dementia (Alzheimer's Association, 2013) (*see* Alzheimer's Disease, Neural Basis of). The biomedical sciences have found countless ways to manage the symptoms of human diseases, but managing a disease is not the same as curing a disease. Saving people who would otherwise have died has given loved ones more time to share together, but it has also produced a large number of older people struggling with multiple chronic health issues that put them at high risk for frailty and disability. Humans have exploited the natural world to meet our needs, but in so doing have degraded the ecosystems of the earth that are essential to maintain our own health.

Continually increasing life span is not biologically sustainable. The concept of a biological warranty period was used to identify a boundary between normal operation and extended operation. It is also a transition from an expectation of health and vigor to a period where continued life span extension meets resistance from the failures of an imperfect biology that eventually overwhelm even the most effective interventions. This is a new dilemma for our species. Technology has extended life span beyond its normal operating limits. End of life has become blurred, and philosophers and ethicists continue to debate whether death should be allowed to follow its natural course or whether life should be held onto at all costs. These are big questions and they do not have simple answers.

When our intellectual energies are focused on extending life span, we forget the important message that Bernice Neugarten (acclaimed sociologist) and Bob Butler (the first director of the

National Institute on Aging) constantly emphasized, namely, the goal of human technology should be to increase healthy life span even if duration of life remains unaltered. A secondary benefit of increasing healthy life span is that quality of life will also be improved. Finally, in an age when technology can defy both disease and death, we must constantly remind ourselves of the risk that we may be trading off longer life for worsening health.

Abstract

'Old age' and 'centenarian' refer to a social representation of an individual based on age. The assimilation of the retirement age to the beginning of old age is confusing because all pensioners cannot be assimilated to oldest old. Old age, as the last phase of human life, must be studied more specifically by questioning the factors that contribute to achieving this phase of life, the habits of this age group, and their possibilities of aging well. Moreover, in the framework of a social and behavioral paradigm, studying old age involves thinking of the role of the elderly in society.

The words 'old age' and 'centenarian' refer to a social representation of people based on age. Age is a chronological information (duration) that corresponds to the number of years lived since birth. Based on this definition, an individual could be considered as a centenarian if his or her life duration is equal to 100 years. In contrast, the term 'old' does not refer directly to any given chronological age. Basically, old age corresponds to the life phase lived by the old people. The issue is to define who these old people are, which involves answering the question when does old age begin or when and how an individual could be considered as old.

Before defining old age and what qualifies someone as old, it is questionable whether these concepts are found in all societies. Cross-cultural studies reveal that in some cultures, as for example, Cuiva of Colombia, the concept of old people does not exist. Once people become adults, they keep this status until their death. This is probably why Sokolovsky (2009), in the introduction of the book *The Cultural Context of Aging*, wrote "the conception of being old is *near* human universal".

However, a historical approach indicates that in most societies, human life is conceived of in three phases: childhood, adulthood, and old age. These three phases of life are mainly defined by the ability of individuals to perform the necessary survival tasks for themselves and their group. These tasks are culture specific. Thus, childhood would be the age at which the individual is 'too young' to accomplish the tasks for adults and 'old age', the age at which the individual would be too old. Modernity has substituted the notion of paid work to 'tasks necessary for survival'. Consequently, the official retirement age could be likened to the 'old age' beginning.

When Does Old Age Begin?

Janet Roebuck (1979) asked this question in 1979. Her historical reconstructions conducted mainly in England showed the vagueness of the concept of 'old age'. Under the influence of the Elizabethan Poor Law, it appears that a person is considered old if two conditions are met: reaching the age of 50 or 60 years and being unable to support oneself. In the years 1880–90, the need to match a chronological age to the concept of old age has been raised by the discussion on a state of old age pension scheme. As the combination of age and function would not lead to uniformity, a determination of chronological age was required. Considering the variety of ages selected from other European countries, 65 years was mentioned to be in correspondence with public opinion. However, the debate around the beginning of old age (and the corresponding pension) in the nineteenth century has been subjected to different types of arguments. Considering the age of 70 years as the beginning of old age was a way to save money for pensions. On the opposite side, social arguments were that some professions make people age and die more quickly than others. The age of 70 years was held in 1908, mainly for economic reasons. Subsequently, the pension age was lowered to 65 years for men and 60 years for women without even clearly defining 'old age'. Today, this chronological age is still associated with the beginning of old age in the collective representations. More than 30 years after the work of Roebuck, in France, B. Ennuyer (2011) asks nearly the same question "*A quel âge est-on vieux*". Citing several surveys on the representation of old age by different age groups, the author shows the subjectivity of the concept of 'old age'. For example, people aged between 15 and 25 years considered the beginning of old age around 60 years, while retired think that old age begins at 79 years. The author argues that the definition of old age is still very determined by official statistics and this contributes to a kind of reification.

Increase in Life Expectancy

During the twentieth century, life expectancy increased by 30 years or more in most developed countries. This general trend of longer life goes on with a reduction in mortality at older ages. In these countries, 60-year-old people benefit from more than 25 years of life. This increase in life expectancy contributes to a huge increase of oldest old people. In 2012, there were 17 087 centenarians and 561 646 nonagenarians in France, while these individuals were, respectively, 200 and 35 000 in 1950 (Balard et al., 2011). Old people and oldest old are becoming more numerous and reaching old age is becoming common. Some studies consider that for such countries, most babies born since the year 2000 could become centenarians (Christensen et al., 2009).

This demographic trend is the first upheaval in the way of conceiving the 'old age'. Indeed, the assimilation of the retirement to the beginning of old age, considered as the death-waiting life phase, is no longer valid. In this context of longer life, demographers, epidemiologists, and other biomedical researchers pay close attention to healthy life expectancy and life expectancy without disability (Robine et al., 2013). This research shows that the increase in life expectancy is accompanied by an increase of health expectancy. Despite the fact that this contributes to postponing the years lived in poor health and disabilities later in life, it is not possible to conclude to a generalization of the morbidity compression (Crimmins and Beltrán-Sánchez, 2011).

Fragmentation of the 'Old Age' Life Phase

The survival rate after 60 years, the increase of health expectancy beyond this age, and also the lifestyle disparities of old people have led to a fragmentation of the 'old age' phase into several phases. Thus, Laslett (1991) distinguished the Third Age and Fourth Age, while Neugarten (1974) referred to three categories of old people, the young old, the old old, and the oldest old. It is complex to match fixed chronological ages with these categories considering that the boundaries should fluctuate if we consider the increase of life and health expectancies. However, conventionally, people of the Third Age are those whose age is between 60 and 80 years and those of the Fourth Age are those over 80 years old, even if we find variations of 5 years of these boundaries. It is the same kind of chronological benchmark for the young old (65–75 years), old old (75–85 years), and oldest old (85+) people.

The Third Age and the young old categories are described by researchers as a new kind of old people. They are retired and they do not suffer from any incapacitating disease. These individuals are described as socially active and leisure consumers. Within the family, they are a pivotal generation. They can contribute to help their children financially and take care of their grandchildren and they can also provide a caregiving role with respect to their elderly parents.

Persons belonging to the Fourth Age category represent the 'real' old age because they suffer from comorbidities and activity limitations. From a demographic point of view, Baltes (1997) proposed to consider the Fourth Age as the chronological age where 50% of the birth cohort has died. Thus, the oldest old are part of the category of the Fourth Age and could be defined as those who exceeded the life expectancy of their birth cohort. The old old is an intermediate category between these two broad age categories, even though these categories are not perfectly homogeneous considering that it is possible to be 90 years old without being affected by any activity limitation. In addition, the concept of frailty (Morley et al., 2013) now appears to be crucial to establish distinctions among the elderly population.

From a social and behavioral point of view, it is not appropriate to give a chronological age to the beginning of old age because the social representation of old age depends on the population and the culture considered. The aging process is not only an individual and biological phenomenon but also a social phenomenon that permits to distinguish the oldest old from the other.

From social and behavioral perspectives, it is possible to distinguish three main issues related to old age and centenarians: the means to achieve old age, the old age habits, and the sociocultural meaning of old age.

Achieving Old Age

Despite the increase of lifespan and the oldest old population, reaching old age and becoming centenarian remains a mark of distinction. Consequently, one of the major research axes is the identification and the analysis of the longevity factors. All disciplines interested in human lifespan explored what allowed some people to reach old age with their own models and methods. Thus, the hypothesis of a genetic heritability of longevity has been largely explored as in the context of twin studies (Herskind et al., 1996). Given the relatively small proportion of the genetic heritability of longevity, these types of research are mainly focused on the biological factors that contribute to healthy aging (Skytthe et al., 2011). Social and behavioral sciences also present interesting results in this research field. Psychological researches show particularly strong links between personality traits and longevity (Chapman et al., 2011). These studies show such good evidence that higher level of conscientiousness and lower levels of hostility and 'distressed' personality are associated with greater longevity. Researches in public health, epidemiology, sociology, and anthropology have focused on the benefit of the sociocultural influence. Several studies have demonstrated the strong influence of the social status on life expectancy (Marmot, 2004).

Some researchers have attempted to analyze the lifestyles of populations in which the number of centenarians appears significantly higher than the national average, as in Okinawa and Sardinia. This allowed them to highlight, among other things, the influence of a low-calorie diet (Willcox et al., 2006) and physical activity (Pes et al., 2011) on the duration of human life.

Finally, the health gender paradox has to be mentioned as a key issue in this field. Even if women live longer and are more numerous in old age, men are in better physical and cognitive health, and are higher functioning. This observation implies to ask: if better health should lead to a longer life, why are men not living longer than women? Biologic research tries to answer this by focusing on the physiological differences between male and female, while social and behavioral research are mainly focused on the gender differences that could explain the stronger selection effect for men than women (Balard et al., 2011)

Aging Well

Research on longevity and aging are inseparable from the question on aging well, as evidenced by the myths or the first philosophical reflections such as those of Plato and Aristotle on the idea of positive aging for the first one and negative for the

second one. The fundamental question underlying this debate concerns the quality of life in old age, or to put it more directly if the years lived in old age are worth to be lived. Gerontology research debated on the aging well topic by developing concepts such as successful aging, active aging, productive aging, etc.

Despite the variety of definitions, the assessment of successful aging or quality of life in old age appears to be done mainly through the concepts of health, functional autonomy, and social productivity. Fernández-Ballesteros et al. (2013) indicate "Health maintenance and ADL preservation; high physical and cognitive functioning; positive affect and control, and social participation and engagement seem to be the most accepted domains." This aging well conception corresponds to the theoretical model of activity theory (Havighurst, 1961), which could be summarized in the preservation of the middle age lifestyles. The work of Rowe and Kahn (1987) is certainly the one that has most influenced this model by comparing usual aging to successful aging.

Some authors such as Tornstam (1992) criticized this paradigm based on productivity, efficiency, and independence as a kind of scientific realization of the middle-aged white Western men's values.

In contrast to the activity theory, the disengagement theory (Cumming and Henri, 1961) is mainly a psychological research paradigm. This model suggested that gradual disengagement from social life and focus on the inner self was a naturalistic process of human aging, because physical and mental decline is inevitable. Based on this paradigm, psychologists have developed several theories of successful aging. The Selection, Optimization, Compensation theory of Baltes (1997) has become a major model for this research field. It assumes that old people actively cope with losses by using selection (choosing their life goals), optimization (sophistication of ability, allocation, or adjustment of resources and regulation of motivation to accomplish goals), and compensation (drawing on a compensative resource, such as assistive devices or new strategies). The socioemotional selectivity theory (Carstensen, 1991) hypothesizes that individuals of any age focus on emotional euthymia rather than stressful situations, such as seeking new information or knowledge, when they realize that their life is limited. The gerotranscendence hypothesizes that gradual and natural changes in behavior and thought that come with aging provide an adaptive mechanism through which the elderly can maintain psychological well-being (Gondo et al., 2013).

Disengagement theory has also had some influence on the field of sociology of aging and the development of the concept of '*déprise*', which focuses on the arrangements and strategies made by old people when they are confronted with social and physiological trials (*épreuves*) (Caradec, 2007).

Old Age Habits

The analysis of the old age experience is not limited to the issue of aging well. It also aims to understand old people as different from younger people. In this context, particular attention should be paid to distinguish the biological age effects and the generation effects on life.

The aging process, whether we conceive of it in its biological and/or social dimension, is not sufficient to explain the specific behavior of the oldest old. In order to cope with the inherent fragility of senescence and the specific social events of this phase of life (isolation, loss of empowerment, etc.), the oldest old mobilize resources and tools that are often indicative of their generational affiliation. Generation constitutes a fairly narrow circle of individuals who, despite the diversity of other factors that have to be taken into account, are connected in a homogeneous whole in that they rely on the same main events and changes during their receptivity. In this context, all the research linked to the material and social environment of the oldest old must take into account the generational influence. Thus, the attitudes that they have with their health, their place of life, the technological equipment, the professional care as well as family relationships, and many other elements are strongly influenced by generational membership. This implies that precise attention should be paid to the particularities of the cohort studied and people's life course. A corollary of this is the almost permanent question on the results and theories developed regardless of the line of research considered. Indeed, it is likely that the baby boomers, i.e., the cohorts born after World War II, will report profoundly different behavior than the present-day centenarians.

The Sociocultural Meaning of Old Age

As indicated by Carstensen and Fried (2012), "population ageing presents a cultural problem". The increasing figures of the oldest old constitute an economic and health issue that is exacerbated in the present context of economic and social crisis in many societies. In addition, the changes in intergenerational relationships when they take the form of a decline in family support may lead some old people to a huge precariousness (Zhang, 2009). However, the social challenge related to old age is not limited to its economic and health dimensions. Indeed, it implies to question the meaning that our society is willing to pay to old age. In a social and behavioral perspective, one of the fundamental questions asked by old age is the social role of the oldest old people in our society. However, the place and the social role of oldest old is undermined by the movement of society medicalization that contributes to assimilate aging and senescence, making the old age inconsistent with the dominant values in modern societies such as productivity. Similarly, grouping presenile dementia and senile dementia under the term 'Alzheimer's disease', leads to a massive increase of 'illderly' (Ballenger et al., 2009), which contributes to the construction of a negative image of old age. Changing the perspective that we have of the oldest old now appears as a crucial issue as well as leads to research to improve their health and functioning. In this view, it seems necessary to remember that in some cultures, old age is not synonymous with senescence and obsolescence, but is rather a privileged status inherent to the experience and knowledge accumulated.

Abstract

To understand how to raise labor force participation of older workers, it is necessary to understand demand, supply, and institutional factors. Labor supply and retirement decisions of older workers are at the core of microeconomic research and many countries have recently reformed their pension systems to make early retirement financially less attractive. Noneconomic factors like quality of work, health status, social networks, and peer group behavior are important as well. The demand side of the labor market is equally important, particularly now that recent pension reforms have raised labor supply.

Key questions are: How to maintain the productivity of older workers? How to eliminate existing prejudice toward older workers among employers and coworkers? How effective are laws against age discrimination or public campaigns to promote the image of older workers? Which demand side adjustments will be necessary to accommodate an increased supply of older workers, concerning, e.g., hiring policies, reducing wage costs, training of older workers, using alternative exit routes, accommodating workers with a health problem and facilitating gradual retirement?

In this article, we discuss the labor force participation of older age groups. We discuss definition and measurement of old age and work participation and present some data on OECD countries, provide an overview of the determinants of retirement and labor supply of older age groups, and summarize what we know about labor demand and productivity. We also discuss policy issues that may guide future research.

Introduction and Background

The increase in life expectancy in recent years poses new challenges for policymakers across the world. Policymakers faced with unprecedented rises in social expenditures on those in retirement and the need to ensure fiscal sustainability of social welfare and pension systems, have endeavored to extend working careers by attaining higher employment rates among older workers. In particular, many countries of the European Union face the challenge of reversing the trend toward early retirement by providing financial incentives to make people remain in work longer. This policy agenda requires a good understanding of demand and supply factors underlying the labor force participation of older age groups.

Since 1999, active aging has featured often in many of the EU policy frameworks. The goal of active aging has often been narrowed to extending working lives and discouraging early retirement. The focus on enhancing labor market participation of older workers is reflected in two EU-level targets: the 2001 Stockholm target to ensure that half of those in the age group of 55–64 years were in employment by 2010, and the 2002 Barcelona target to increase the average age of exit from the labor market (for retirement) in 2010 by 5 years. While none of the EU countries has managed to achieve the Barcelona target, Germany, Ireland, Cyprus, the Netherlands, and Finland did raise the employment rate for the age group of 55–64 years to over the 50% threshold by 2010 (Zaidi and Zolyomi, 2012). (In Sweden, Denmark, Portugal, and the UK the employment rate of this age group was already above 50% in 2001.)

Under the European Union's strategy for smart, sustainable, and inclusive growth, known as 'Europe 2020,' one of the five headline targets that EU Member States have agreed to implement to increase the employment rate of 20- to 64-year-old individuals to 75% by 2020. This target can only be achieved by increasing the employment rate of older workers and raising the effective retirement age. Another target is to lift at least 20 million people out of poverty and social exclusion in the next decade. This involves ensuring adequate pensions for older people, for which extended working careers are essential. In line with Europe 2020, the European Employment Strategy also promotes policies and measures targeted at supporting longer working lives. The Europe 2020 New Skills for New Jobs flagship initiative emphasizes better training and skills through occupational training and lifelong learning opportunities, among others for older workers (Zaidi, 2012).

The idea of the Silver Economy offers a solution to the current economic problems of lack of growth in the European economies exploiting the potential of a rising share of older people in society. It refers to the fact that the rising share of older consumers represents a potential for additional demand for new types of products and services, such as personalized care and technology that enables people to maintain healthy and independent lives as they age. Furthermore, the new cohorts of retirees are also expected to be wealthier than their predecessors, and thus generate more specific demand in the economy. The term 'Silver Economy' also sometimes encompasses the rising segment of older workers who ought to be considered as a resource for their employment potential and other social contributions (such as transfer of skills toward younger workers) in bringing economic growth.

To understand how to raise labor force participation of older workers, it is necessary to understand demand, supply, and institutional factors. Labor supply and retirement decisions of older workers are at the core of microeconomic research and many countries have recently reformed their pension systems to make early retirement financially less attractive. Noneconomic factors like quality of work, health status, social networks, and peer group behavior are important as well. Health plays a major role, in particular through limitations at work due to ill health and disability. The demand side of the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.94040-6

labor market is equally important, particularly, now that recent pension reforms have raised labor supply.

Key questions are: How to maintain the productivity of older workers? How to eliminate existing prejudice toward older workers among employers and coworkers? How effective are laws against age discrimination or public campaigns to promote the image of older workers? Which demand side adjustments will be necessary to accommodate an increased supply of older workers, concerning, e.g., hiring policies, reducing wage costs, training of older workers, using alternative exit routes, accommodating workers with a health problem and facilitating gradual retirement?

In this article we discuss the labor force participation of older age groups. First we discuss definition and measurement of old age and work participation and present some data on OECD countries. Then we provide an overview of the determinants of retirement and labor supply of older age groups, followed by a summary of what we know about labor demand and productivity. Finally, we discuss policy issues that may guide future research.

Old Age

At least three definitions of old age are in use in the social gerontology and economics of aging literature:

- Subjective definition – based on each individual's own assessment, usually derived from their labor market activity or health status.
- Functional definition – using objective information on how people function, considering restrictions due to health problems and frailty in different domains of life (e.g., in being employed, in physical and mental functioning in their day-to-day life).
- Chronological definition – using an objective age threshold beyond which the old age phase of life begins (e.g., the statutory pension age).

These definitions can provide an approximate entry into the old-age period of life around the time of retirement from the labor market or deterioration in health status. The chronological age cut-off can also be defined on another basis. For instance, the employment rate of older workers by EUROSTAT (the Statistical Office of the European Union) is calculated using the age group of 55–64 years. This age group is the primary focus of analysis in this article and in most of the literature on labor force participation of older age groups.

In addition, there is an increasing trend to work beyond the statutory retirement age (often age 65). Such workers are often referred to as 'silver workers.' Silver workers are increasingly visible in every sphere. In the UK, for instance, the most obvious examples include Queen Elizabeth (age 86) Sir Alex Ferguson (manager of Manchester United until age 71), and the actress Dame Judi Dench who competed for the Golden Globes at age 78. Employment after the statutory age is of special interest as it may provide a necessary complement to income and thus avoid poverty in old age. The financial aspect is not the only factor, however, as higher income workers are often overrepresented among post-retirement workers (Giarini, 2009). A formal job after retirement also serves as a possible means to remain active in other social and civic engagements.

One advantage of the chronological age definition is that age is by definition an exogenous attribute, whereas indicators of old age on the basis of labor market or health status are often affected by individual choices. An adoption of the definition on the basis of the chronological age will allow us to capture diversity within the old-age population in terms of their labor market participation (i.e., the endogenous variables). Moreover, the chronological definition is free from negative biases that arise from common myths and misconceptions about aging and older people, such as the perception that they are often frail, ill or disabled, and may thus be a burden on the community.

Work Participation

Individuals can be classified in three categories: employed, unemployed, or economically inactive. The most common definitions for these follow the Resolution of the 1982 International Conference of Labor Statisticians known as the 'ILO guidelines' (ILO, 1982). Two important elements are the selection of an age group (the reference group), and the time unit of the assessment (the reference week):

- Employed persons comprise those aged 15 years or above who either (1) worked for pay, profit, or family gain for at least 1 h during the reference week or (2) were not at work during the reference week but were temporarily absent from their job or business. This definition is applicable to employees, self-employed persons, and family workers. Pay includes cash payments or/and payments in kind (that is, in goods and services).
- Unemployed persons comprise those of ages 15–74 years who are: (1) not employed according to the definition mentioned above, (2) currently available for work (i.e., for paid employment or self-employment before the end of the 2 weeks following the reference week), and (3) actively seeking work (i.e., had taken specific steps in the 4 weeks ending with the reference week to seek paid or self-employment).

In some countries, the reference group is defined slightly differently. For instance, in Spain and Great Britain, the reference age group corresponds to those 16 years and more, while the upper age limit for the reference group is restricted to 74 years in Denmark, Estonia, Hungary, Latvia, Finland, Sweden, and Norway.

The residual third group is commonly referred to as 'inactive.' For older people, however, the distinction between unemployed and inactive is often blurred (Marin, 2013). For example, 'discouraged workers' who lost interest in searching for a job are categorized as 'inactive' rather than 'unemployed.' The most useful distinction for the analysis in this article is, therefore, employment versus nonemployment.

Employment Rates of the Age Group 50–64 Years

Figure 1 (males) and 2 (females) show large differences in the employment rates of workers aged 50–64 years across countries

Figure 1 Employment rate for males, in the age group 55–64 years, during 2000 and 2009.

Figure 2 Employment rate for females, in the age group 55–64 years, during 2000 and 2009.

in 2000 and 2009. For males in 2009, some countries had employment rates of older workers close to 80%, whereas in other countries it was less than half as large (Hungary, Turkey, France, and Poland). Still, most countries improved in comparison to 2000. This positive trend seems to have stopped since 2009 (Zaidi and Zolyomi, 2012, Figure 6) as an effect of the global economic crisis since the fall of 2008. The trends for an earlier period (1998-2005) also show rising trends of employment among older workers (see Zaidi et al., 2007 for more discussion).

For older females, Iceland, Sweden, New Zealand, and Norway show employment rates in excess of 60%, and Switzerland, Finland, Estonia, and the United States lag only slightly behind (around 60%). At the other end of the spectrum, Turkey (16%) and Poland (22%) performed worst in 2009. In comparison to the trends for males, the improvement in the employment rate for female older workers is larger and observed in more countries. Still, the employment rate of older females remains quite low in many countries.

The Netherlands, Germany, and Finland are examples of countries where the employment rates among older workers have risen considerably because of specific policy measures. In the Netherlands, three public policy drivers are viewed to be responsible for these trends (Euwals et al., 2009): (1) Elimination of financial disincentives to delay retirement and make the pension system actuarially fair; (2) Measures to keep (older) people with reduced work capacity in the labor market instead of granting them permanent invalidity benefits; and (3) Other relevant policy measures such as stricter job search requirement for unemployed older workers.

In Germany, two partial retirement schemes (the partial retirement (Altersteilzeit) and the partial pension (Teilrente)) aim to provide a gradual transition from working life to retirement. Employees can claim a partial retirement if they have reached age 55 and wish to reduce their working time to half of the collectively agreed hours and if the employer agrees. Until 2010, the employer could receive subsidies to cover the costs if the part-time job is filled with a previously unemployed person. The partial pension can be 33, 60, or 67% of the full pension, but take-up of this pension is much lower than that of partial retirement.

In Finland, the 2005 reform of the earnings-related pension system introduced flexibility regarding the time of retirement between the ages 63 and 68 years. Within this age range, incentives to delay in retirement are given by higher accrual rates. From age 18 to 63 years a pension right of 1.5–1.9% of the pensionable wage is acquired each year. From age 63 until age 68, it is possible to receive an old age pension, but the

accumulation rate increases to 4.5% annually, creating a strong incentive to remain at work. If the old age pension is further deferred after age of 68 years then the amount is increased by 0.4% per month. These incentives had a strong impact, increasing the effective age of retirement.

Figure 3 (males) and 4 (females) show how the ratio of employment rates of older (aged 55–64 years) and prime-age (aged 35–44 years) workers have changed between 2000 and 2009. They show that in most countries the relative position of older workers compared to younger workers (both males and females) has improved. An exception is Turkey, where the employment situation among older female workers has deteriorated between 2000 and 2009. For Turkish males, there is also a decline in the relative position of older workers, but much less stark than for females.

The reforms across European countries are characterized by two broad types of policy measures:

1. Promotion of employment of older people, through financial incentives for work in the pension and old-age social security systems and through phasing out early retirement schemes, and by raising retirement ages or abolishing the mandatory retirement age; and
2. Improvement of conditions for the recruitment, retention, and productivity of older workers. This involves age management policies at the company level; public measures for the improvement and modification of qualifications and competences; reductions in labor costs of employment of older workers, and active labor market programs.

Figure 3 Ratio of employment rates for older workers (55–64) and younger workers (35–44), for males, during 2000 and 2009.

Figure 4 Ratio of employment rates for older workers (55–64) and younger workers (35–44), for females, during 2000 and 2009.

Many countries have successfully implemented the first type of policy measures during the late 1990s and early 2000s, and have now embarked on complementing them with the second type (European Commission, 2012). A good example is Poland, which after successful pension reforms, has now prepared a comprehensive program ('Solidarity across generations. Measures aiming at increasing the economic activity of people over 50') to achieve the Lisbon employment rate target of 50% for the age group of 55–64 years by 2020.

Labor Supply of Older Workers

At least three supply explanations for the large variation in retirement patterns across countries have been given (Kapteyn and Andreyeva, 2008). The first is financial incentives, emphasized by a group of researchers performing country-specific studies using a harmonized methodology (Gruber and Wise, 2004), evaluating the link between old-age social security programs and national retirement patterns. These studies consider the substitution effect as the dominant factor in shaping individual choices in the income–leisure trade-off: a higher reward for working longer raises the price of leisure around the retirement age, and therefore reduces the demand for leisure and increases labor supply. They emphasize that in many systems, retirement benefits did not increase with delaying retirement, so that the implicit tax on continued work was often 100%.

To illustrate: Gruber and Wise (2004) summarize their results of a hypothetical pension reforms in 12 countries, based upon a common model. The reform (named *Three-Year Delay*) shifts all pension entitlements by 3 years (if the actual entitlement at age X is Y, the simulation assigns entitlement Y to age X+3). They compute by how much the percentage out of labor force changes for a country-specific age group around retirement (the first age at which at least 25% of the workforce is out of the labor force plus the next 4 years). The results show that retirement behavior is sensitive to financial incentives: in 11 of the 12 countries, nonparticipation in the age group considered falls by more than 40% if pension entitlements are shifted by 3 years. Many other empirical studies have confirmed the sensitivity of retirement for financial incentives, with empirical strategies varying from reduced form difference-in-differences approaches to sophisticated structural dynamic programming models (e.g., French and Jones, 2011).

Another explanations for cross-country differences and particularly the gap between the United States and many European countries are based upon the larger extent to which home production can be substituted with services available in the labor market (Freeman and Schettkat, 2001), differences in personal preferences or culture (Blanchard, 2004), or the power of unions (Alesina et al., 2006).

A discussion of retirement patterns also has to consider the role of health. Failing health may lead to retirement (Kalwij

and Vermeulen, 2008). Retirement status may also have a (positive or negative) influence on health: it can remove mental stress and physical work effort, but may also be a life event that creates stress and reduces health. Existing studies often find a negative effect of retirement on, in particular, cognitive functioning, as a result of living less stimulating lives in retirement compared to working lives (Rohwedder and Willis 2010; Bonsang et al., 2012). An economic framework for studying the relation between health and retirement is the Grossman model (Grossman, 1972) in which individuals derive utility from consumption and health, and health also influences earnings. Galama et al. (2013) introduce variants of the basic Grossman model that include a retirement decision. Here individuals with lower human capital have fewer resources to invest in health so that their health deteriorates faster, implying that health will be positively associated with income and education. A higher earnings capacity also induces people to work longer, as observed in many studies. Yet, at the same time improvements in health over time have an income effect that reduces work effort and hence explains trends in early retirement.

The Demand for Older Workers: Productivity, Wages, and Substitution

Of the models that predict the demand for older workers from the firm's perspective, the best known is Lazear's 'delayed compensation contracts' model (Lazear, 1979). Lazear argues that a work contract where the worker is paid less than the value of the marginal product at younger ages, and more at later ages, has advantages for both workers and employers. For workers, this type of contract will increase lifetime wealth. Employers, although forced to bear the higher fixed costs associated with delayed compensation, gain from improvements in performance and stronger employee commitment induced by the workers' fear of losing delayed compensation. Mandatory retirement is required as a way of terminating the contractual work, as the worker would not voluntarily retire due to the high wage. In this model, firms avoid hiring older workers, as this will reduce the possible benefits of delayed compensation.

Skirbekk (2003) summarizes earlier studies relating age to productivity, finding evidence of a decline in several aspects of physical and mental functioning from around age of 50 years. On the other hand, other studies argue that older workers often rely on their professional experience to adapt and compensate for the decline in physical and mental ability and find no significant difference between the job performance of older and younger workers. Recent studies using matched employer–employee data suggest that individual productivity declines with age in some dimensions, but the decline can be partly compensated by experience, personal aids, and suitable workplace adjustments (Crépon and Aubert, 2003). In a study for Belgium, Lallemand and Rycx (2009) find that, particularly in ICT firms, young workers are significantly more productive than older workers, although age effects on productivity have substantially decreased over time. Empirically, higher wages for 55- to 64-year-old individuals relative to 25- to 29-year-old individuals are negatively correlated with activity rates at the age of 55–64 in the case of both men and women (OECD, 2006), in line with the firm's disincentive to employ older workers if productivity rises less with age than wage costs.

In view of the current context of high youth unemployment in many European countries, it is important to dispel the myth that a longer working career would imply less employment opportunities for younger people. The idea that the old should make place for the young is based on the incorrect notion that the total number of jobs is fixed (the 'lump-of-labor' fallacy). The same argument was used in the past to discourage women from joining the workforce and to motivate anti-immigrant policies. The lump-of-labor fallacy seems to pop up over and over again in the policy debate and becomes a serious concern for the intergenerational conflict. Evidence against it comes from the stylized facts that the high-employment rate among older workers (55–64) is typically positively associated with the high employment among youth (15–24). If the lump-of-labor arguments were correct, the opposite would be expected. Readers are referred to Kapteyn et al. (2004) for more rigorous empirical research supporting this line of argument.

The skills offered by older people are very often distinct and cannot always be substituted by those of younger workers. For instance, patients tend to prefer older physicians and older retail assistants often are more knowledgeable and patient. Earlier retirement, therefore, will probably not generate more jobs for young entrants. Instead, using the full potential of older workers and reaping the benefits of the demographic shifts in the demand for products and services will create more jobs both for the old and the young (Zaidi, 2012).

Employer Attitudes, Age Discrimination and Regulation

A special Eurobarometer survey (European Commission, 2007) shows that almost half of the population feels that age is, together with the onset of a disability, one of the most important criteria that might put a job candidate at a disadvantage when competing against someone with the same qualifications: 78% of respondents feel that a person aged 50-plus is less likely than a younger person to get a job, accepted for training, or promoted.

In a survey of 500 large employers in the UK, Taylor and Walker (1994) show that many had negative stereotypes of older workers, especially with regard to their openness to training and ability to adapt to new technologies. Laboratory and field experiments confirm that employers discriminate against older applicants (Riach and Rich, 2002). More recent studies show mixed results. For example, McNair et al. (2007) found that age stereotypes and attitudes tend to favor older workers in general (emphasizing more skills, life experience, reliability, loyalty, etc.) though negative views also exist (e.g., lack of willingness to adopt new work methods). Ilmarinen (2006) emphasizes the need to change toward a work culture that is better suited for workers of all ages, involving employers and employees as well as society. Van Dalen et al. (2009) analyze employer attitudes and actions in Greece, Spain, the Netherlands, and the UK and find that only in the UK, older workers are recognized as a valuable source of labor

supply. Vickerstaff (2010) summarizes the literature on this topic and concludes that most organizations have no specific strategies for age management and that the business case for a well diversified age composition of the workforce is extremely fragile, particularly during recession. Karpinska et al. (2013) find that Dutch managers generally do not find it important to keep older workers until the mandatory retirement age.

Cheron et al. (2011) extend the standard model of equilibrium unemployment with an explicit role of age. They argue that a standard retirement age explains the lower employment rate among the older population: it reduces the willingness of firms to recruit older workers, as expected returns will be lower. Moreover, the shorter expected job duration reduces the tendency of older workers to invest in job search. They conclude that existing policies in many countries present strong perverse effects on employment and social welfare.

There are several empirical studies on the impact of employment protection legislation. Bassanini and Duval (2006), using data from 21 OECD countries for 1982–2003, find a positive relation between employment protection legislation and the employment rate of workers aged 55 to 64. OECD (2004) finds that the negative relation between employment protection and the hiring rate of men aged 50 and over is compensated by a decrease in firings.

On-The-Job Training

Jacobs (2010) shows how to systematically analyze the interactions between human capital investments in on-the-job training (OJT), retirement choices and pension saving. The model adds an endogenous retirement decision to the standard life-cycle model of OJT investment and human capital formation. By extending the time-horizon over which investments in skills materialize, a higher retirement age promotes investments in OJT. Later retirement and OJT investment are therefore complementary and generous early retirement schemes therefore indirectly discourage investment in human capital. The intuition is that the opportunity return at which future labor earnings are discounted increases with the retirement age and human and financial capital are substitutes over the life cycle. This analysis implies that promoting lifelong learning or later retirement will not be effective as long as strong disincentives caused by labor market institutions, early retirement schemes and incentives for pension savings remain in place. Moreover, promoting private pension savings may inadvertently create implicit taxes on skill formation and indirectly stimulate early retirement, thereby worsening the aging problems.

Empirical work analyzing OJT of older workers is scarce. A major empirical problem is that investment in OJT is very difficult to measure. According to Heckman (2000) most training is informal rather than formal, limiting the applicability of commonly employed training measures, which are often based on subjective data (from firms or employees), on formal OJT investment. Moreover, firms and employees have different views on the participation intensity of training (Leuven, 2005). Not only the costs (i.e., the OJT investment), but also the returns (future wages) are difficult to measure, because earnings are not equal to labor productivity even if labor markets are perfectly competitive (since time investment in OJT drives a wedge between gross labor productivity and gross earnings).

Policy-Related Research Questions

Some major policy relevant research questions concerning old-age work participation in OECD countries are the following:

Which Economic and Noneconomic Factors Drive labor Supply of Older Workers?

Studies on the consequences of introducing and abolishing generous early retirement arrangements in many countries have shown that retirement decisions are sensitive to financial incentives. The quantitative importance of other factors (health, job characteristics, family considerations, peer group effects, etc.) is less clear.

What Are the Advantages and Disadvantages of Gradual Retirement?

Gradual retirement, in the form of either phased retirement reducing hours in the career job, a less-demanding bridge job, or self-employment, is more common in the United States than in Europe. It potentially offers an opportunity to keep people attached longer to the labor market.

What Are the Consequences of Working Longer for Well-Being in Old Age?

It seems clear that working longer may reduce old age poverty if it also leads to higher pensions, but studies on the consequences for health and cognitive skills seem inconclusive.

How can Negative Employer Attitudes toward Older Workers Be Eliminated?

Negative stereotypes and prejudice against older workers are diminishing but are still strongly embedded in society. Positive employer attitudes are often not translated into actions. How effective are legislation against age discrimination and public campaigns promoting a more positive view of older workers?

How Can Lifelong Learning be Promoted?

The effectiveness of investment in skills of older workers depends on how long these workers remain employed, leading to important relations between human capital investment, productivity, retirement saving, and early retirement arrangements.

What Is the Relation between Labor Market Flexibility and the Position of Older Workers?

Compared to the United States, European labor markets are characterized by larger employment protection, less job mobility, longer durations in jobs, and lower hiring rates of older workers. Would removing institutional restrictions and increasing flexibility improve their position?

Does the Economic Crisis Affect the Relevance of Existing Policy Recommendations?

The increasing unemployment rates (among young workers in particular) should not reduce the political pressure on increasing participation of older workers. It is important to dispel the myth of work sharing that early retirement would generate employment for younger workers.

Conclusions

All in all, we know more about labor supply of older workers than about their demand and productivity. Financial incentives matter for retirement decisions, though other, noneconomic factors like job satisfaction, health, working conditions, and attitudes of employers and coworkers also can have important effects. Still, more work is needed on, e.g., joint retirement decisions of husbands and wives, gradual retirement, substitution between exit routes, the interplay between economic and noneconomic factors, etc. Cross-country analysis exploiting the institutional variation seems particularly fruitful. Recent pension reforms in many countries give room for applying quasiexperimental approaches and improved identification of causal effects.

More research challenges remain concerning employer attitudes and labor demand. Good microdata are quite scarce here and the heterogeneous nature of jobs and firms increases the difficulty of this task. Qualitative research using cross-country comparisons suggests that a "coordinated and comprehensive package of age friendly employment measures and policies" leads to the best results (Sigg, 2007), but much more work is necessary to determine what characterizes optimal age management. In particular, the interplay between economic and noneconomic is poorly understood.

Older workers must be attractive to employers, because of their skills, productivity, and wage costs. Attitudes of employers toward older workers vary across countries and have to change in some countries. Subsidies for investing in older workers may help; the effects of employment protection and other features of labor market flexibility and opportunities for self-employment after a career job need to be better understood. Job characteristics, the organization of work, accommodation of workers with a disability and the recognition of the comparative advantages of older workers can contribute to increasing productivity and participation of older workers. In future research, the variation across countries in institutions and institutional reforms can be better exploited to improve our understanding of the mechanisms at work.

Old and New Institutionalism in Economics

David Dequech, Institute of Economics, University of Campinas, São Paulo, Brazil

Abstract

The original (or old) and the new institutionalisms are alive in economics. Both are heterogeneous, dynamic, and thus difficult to define. In addition, despite some important differences, there are also some similarities between them, as well as some complementarity. Consequently the intellectual demarcation between the old and the new institutional economics is not always clear-cut. Sociologically, the original institutionalism has been marginalized in the profession for several decades, whereas some subsets of the new institutionalism have managed to penetrate mainstream economics, partly, but not only, because of a greater degree of mathematical formalization. Furthermore, other approaches that emphasize institutions are also relevant.

Introduction

Although institutions – mostly by other names – had been discussed since the days of Adam Smith and other political economists, institutional economics as such was born in the United States in the early twentieth century, with Thorstein Veblen, Wesley Mitchell, and John Commons as its founding fathers.

According to Malcolm Rutherford (2001: pp. 173–174), this early institutionalism "became a significant element in American economics in the interwar period, only to decline rapidly in position and prestige after World War II." In other words, it became part of – and later was excluded from – what was mainstream economics in America, if one adopts the following definition: "mainstream economics is that which is taught in the most prestigious universities and colleges, gets published in the most prestigious journals, receives funds from the most important research foundations, and wins the most prestigious awards" (Dequech, 2007: p. 281). Also part of American mainstream economics at that time was neoclassical economics, which had emerged in the 1870s in Europe and is a school of economic thought defined by its reliance on the assumptions of (1) utility maximization, as a criterion for rationality, and (2) equilibrium, as the state in which the (micro or macro) economic system under study is or tends to be. It may seem obvious, especially in the eyes of other social scientists, that institutions matter greatly in economic issues, but, for several decades, this was not part of the consensus among economists. Neoclassical economics, in particular, emulated physics and often did not treat economics as an explicitly social science. After World War II, its prominence grew, together with its degree of mathematical formalization. Indeed, it can be argued that its influence grew – at the expense of the original institutionalism, in the case of the United States – largely because it became more mathematical. In the 1950s and 1960s, a specific subset of neoclassical economics, namely standard general equilibrium theory, represented by the Arrow–Debreu model, was very influential and prestigious. This model is substantially ahistorical and noninstitutional, at least in its explicit hypotheses (for a partly similar discussion by a new institutionalist, see Joskow (2008: pp. 1–4), on what he calls neoclassical economics (as distinct from a subset thereof), in the first three decades after 1945). In one of the possible interpretations, the Arrow–Debreu model is intended to be applicable to any economy, in any place and at any moment in time. In a less generalist reading, the model is mono-institutional, as it explicitly assumes only one institution: the market. Moreover, it conceives this institution in an extremely restrictive manner: this is not a market that resembles markets in the real world, but rather an imaginary market, reduced to the price mechanism (the interaction between supply and demand). Other institutions, including a few institutions without which real markets cannot exist, are ignored. Property rights are taken for granted. There are no transaction costs, no information asymmetries, and no binding contracts. The list of goods and services and their respective qualities are perfectly known by every potential buyer. Firms (or self-employed workers–producers) are reduced to a production function, and organizational issues are neglected.

This situation began to change in the 1970s, as economists became increasingly interested in institutions (again). In terms of impact in the profession, a crucial factor in this resurgence of interest was the appearance of the self-identified new institutional economics (NIE). The term 'new institutional economics' was coined by Oliver Williamson in a 1975 book. It was then that the approach originally developed by Veblen, Commons, Mitchell, and their descendants started to be called the 'old' institutional economics (OIE). Both because the adjective 'old' may sound derogatory and because that approach is still alive and has actually been revitalized and improved, the more neutral term 'original institutional economics' is employed here (with the same acronym, OIE).

Neither the OIE nor the NIE is easy to define or to characterize. As a matter of principle, the definitions should be based on ideas. In this sense, the economists who defend a certain set of ideas should be called original institutionalists or new institutionalists. At the same time, communication is not helped by definitions that are very distant from common usage. One must also consider the ideas that are defended by economists who see themselves, and/or are usually seen by others, as members of one of these two subsets of institutional economics. In this second sense, the OIE is that which the original institutionalists do; the same applies to the NIE. However, this does not necessarily amount, in each case, to a consistent group of ideas. In fact, both the OIE and the NIE are heterogenous. In addition, some of the ideas in the OIE may be similar to (and others may be compatible with) ideas in the NIE. As a result of all these complications, the demarcation between the OIE and the NIE is not always clear-cut. In any

 http://dx.doi.org/10.1016/B978-0-08-097086-8.71070-1

case, the label that is usually attached to a work is not as important as the work's intellectual content.

The Original Institutional Economics

The American roots of the OIE can be traced back to the pragmatist philosophy of John Dewey, William James, and Charles Sanders Peirce. This was a strong and distinctive influence, which partly accounts for the originality of the approaches of Veblen, Commons, and other early institutionalists. For Veblen, in particular, Darwin was another major source of inspiration, leading him to propose an evolutionary economics. The term 'institutional economics' was coined in 1919 by Walton Hamilton in an article in the American Economic Review. In the following two decades, the OIE gained considerable prominence in American academia, as mentioned above. Although marginalized in the postwar period, and remaining so until today, the OIE has survived. At first, this happened mostly in the United States, even though European scholars like Karl Polanyi and William Kapp (who both taught at American universities for some time) became influential within the approach, as did Gunnar Myrdal, perhaps to a lesser extent. Authors like John Kenneth Galbraith, Clarence Ayres, Dudley Dillard, and Allan Gruchy were among the main exponents of the OIE in the first decades after World War II (Gruchy referred to this generation as the neoinstitutionalists, but the label is not used often). The OIE even gained an organizational basis, with the creation of the Association for Evolutionary Economics (AFEE), in 1965. AFEE has taken part in the Allied Social Sciences Association annual meetings and, since 1967, has published the Journal of Economic Issues (which is available through JSTOR, journal storage). Many of the scholars who can be called original institutionalists have some connection with AFEE and/or with its journal. Especially after the mid-1980s, the OIE has spread through Europe and other parts of the world.

There is no unified grand theory in the OIE. Hodgson (2004: p. vxii) states that "by 1945 American institutionalism was fractured and diverse, and lacking a consensus on its own methodological and theoretical foundations. Despite the contributions of postwar theorists, these fractured foundations largely account for the failure of institutionalism to re-establish anywhere the prominence that it enjoyed in interwar America." At least two strands of the OIE coexist, one more influenced by Veblen, the other by Commons (Rutherford, 1994: pp. 1–2). They are not necessarily in conflict, but a consensus synthesis does not seem to have emerged yet. Not even an outright rejection of neoclassical economics unites the OIE. According to Warren Samuels (1995: p. 569, n. 2), some institutionalists 'consider [original] institutionalism and neoclassicism to be supplementary.' This seems to be a minority position among current members of AFEE, but historically it has been mostly associated with the Commons' branch of the OIE. Samuels himself defended this view as an eclectic one, which for him did not require internal consistency.

Despite its internal diversity, the OIE can be said to embrace at least three core theoretical ideas (which are variously interconnected and developed within the approach): open-ended evolution, habit, and the strong influence of institutions on individuals.

Veblen was particularly influential in the adoption of an evolutionary perspective combined with the argument that there is no predetermined end to the evolutionary process. Relatedly, the notion of equilibrium, as distinct from process, is not often employed in the OIE. Institutions are the transmission mechanism in the economic evolutionary process. Other evolutionary approaches have been developed in economics, among which the neo-Schumpeterian one is the most compatible with the OIE. Without getting into details about the controversial relation between technology and institutions, one can more vaguely state that technological innovation plays a major role in any original institutionalist theory of economic change.

Habits have been conceptualized in different ways within the OIE. Some authors treat habits as synonymous with habitual behavior, while others see habits as dispositions (inclinations) to behave or to think in a certain way, so that habitual behavior and habitual thought are not habits, but manifestations of habits. In any case, habits imply that not all behavior and thought is completely deliberate and purposeful, in contrast to an influential view in economics. The role of habits has occasionally been overstated by some original institutionalists, which makes it difficult to explain endogenous change. In addition, habits imply some automaticity and inertia. On the other hand, the role of habits is more adequately understood when combined with the notion of bounded rationality, of which the early original institutionalists were precursors (Herbert Simon, who coined the term 'bounded rationality,' acknowledged Commons' influence). Given that the human mind is limited and decision environments are often complex, habits free mental resources from some tasks and thus allow us to make deliberate and sometimes innovative decisions about other issues. From this perspective, habits are not seen as usually opposed to purposeful deliberation nor to innovation, but rather are preconditions for them, although habits can in fact sometimes get in the way.

The OIE is against taking the individual as given in relation to institutions. On the contrary, it argues that individuals are strongly influenced by institutions. We propose below a way of specifying the meaning of this strong influence. In the past, some original institutionalists may have taken this argument too far and fallen into some sort of collectivist determinism. (See Rutherford (1994: pp. 38–42) and Hodgson (1998: p. 181). It must be noted, however, that not all self-identified methodological collectivists or holists have committed this mistake.) Currently there seems to be a consensus within the OIE that individuals and institutions are mutually dependent.

Since its inception, the OIE has been very open to influences from, and dialogue with, other social science disciplines. This may be a defining feature of the OIE (as argued by Gruchy), but it does not differentiate it from the NIE, which is also very interdisciplinary, as explicitly argued by some of its main exponents. What is distinctive of the OIE in comparison with the NIE in this regard is that the OIE is one of the schools of economic thought that are closest to the nonrational-choice approaches in the other social science disciplines.

In methodological terms, the OIE does not share the widespread belief among economists that rigor requires mathematical formalization. This is an important reason why the OIE is not part of contemporary mainstream economics, which is unified by that belief, if by any idea. Some OIE models are mathematical, but most are not.

In political-ideological terms, the OIE is predominantly in favor of an active role of government in planning and regulating the economy, although this need not be seen as a defining feature of the approach, as a few authors who have associated themselves with the OIE had a more laissez-faire orientation. In the interwar period in the United States, original institutional economists reached their peak of influence not only in academia, but also in government. Several of them held important positions during the New Deal.

The New Institutional Economics

Some of the earlier uses of the label 'new institutional economics' may have applied it to transaction cost economics, but the NIE became a much broader and more complex set of approaches. The NIE too has an organizational basis, namely the International Society for the New Institutional Economics (ISNIE), which was founded in 1997. ISNIE has an annual conference, but, unlike AFEE, it does not have its own journal. According to the ISNIE website, "[t]he New Institutional Economics is an interdisciplinary enterprise combining economics, law, organization theory, political science, sociology and anthropology to understand the institutions of social, political and commercial life. It borrows liberally from various social-science disciplines, but its primary language is economics. Its goal is to explain what institutions are, how they arise, what purposes they serve, how they change and how – if at all – they should be reformed." This characterization is quite open in terms of theoretical, methodological, and political ideas. It allows for the presence of different approaches within the NIE, with some important foundational differences among them. In turn, this makes it difficult to refer to the NIE as a school of thought – perhaps even more so than in the case of the OIE.

Transaction costs are an important concept in the NIE and play a central role in the work of Coase (who first developed the notion and its use in the theory of the firm), Williamson and North, among others. Given the importance of these authors within the NIE and the above-mentioned fact that Williamson coined the term 'new institutional economics,' no one would deny that transaction cost economics is a crucial subset of the NIE. It is based, according to Williamson (1985: p. 30), on two behavioral assumptions: bounded rationality and opportunism (self-seeking with guile). In addition to transaction cost economics, other subsets of the NIE also adopt some variant of the bounded rationality hypothesis. This leads us to a controversial issue: the relation between the NIE and neoclassical economics. Depending on how it is interpreted, the assumption of bounded rationality may be either contrasted with, or treated as a special case of, utility maximization. The latter alternative was rejected by Simon. In the former alternative, which opposes bounded and maximizing rationality, substantial parts of the NIE clash in this specific regard with neoclassical economics, as defined above. This seems to be implied by Claude Ménard and Mary Shirley (2005: p. 1), for example, when they state that NIE "abandons the standard neoclassical assumptions that individuals have perfect information and unbounded rationality and that transactions are costless and instantaneous. NIE assumes instead that individuals have incomplete information and limited mental capacity and because of this they face uncertainty about unforeseen events and outcomes and incur transaction costs to acquire information." This means rejecting at least one assumption that is essential for neoclassical economics in any of its variants (and not only the 'standard' one), namely unbounded rationality, which seems necessary for utility maximization. (We will not discuss here whether positive transactions costs and bounded rationality are inevitably linked to one another). Ménard and Shirley (2005: p. 2) insist that new institutionalists "accept orthodox assumptions of scarcity and competition," and thus "NIE does not [completely] abandon neoclassical economic theory" (for a similar statement, but without any references to utility maximization or bounded rationality, see Alston (2008)). Ménard and Shirley seem to define neoclassical economics more restrictively than we do here – perhaps as something similar to the Arrow–Debreu version of general equilibrium theory. For Ménard and Shirley, NIE "has a much broader reach than neoclassical economics, which has been largely concerned with prices and outcomes. … NIE asks questions that neoclassical economics does not address" (p. 2).

So far, we have mentioned the possibility of (partly) opposing the NIE and neoclassical economics and/or differentiating them in terms of scope. Other interpreters, however, identify a neoclassical wing or strand within the NIE. It is true that neoclassical economics did largely neglect institutions for several decades, but such neglect was not implied by the defining ideas of neoclassical economics, namely, utility maximization and equilibrium. On the contrary, since at least the 1970s the neoclassical approach has been extended in order to deal with institutions other than the market, as well as with the market as more than the price mechanism, moving beyond the Arrow–Debreu model in both aspects. In their book-length study of the NIE, Eirik Furubotn and Rudolf Richter (2005) accept that some members of the NIE do indeed adhere to core neoclassical assumptions, especially utility maximization, but Furubotn and Richter claim that this has persisted only at the cost of unsolved inconsistencies in what they call 'hybrid models.' The difficulties in formalizing bounded rationality seem to have played a part in the combination of the new institutionalism and the utility maximization hypothesis, but there exist mathematical models that assume some form of bounded rationality without treating it a special case of utility maximization.

Also controversial is the relation between the NIE and Austrian economics. One of the first books to refer to the NIE in the title or subtitle was a collection of essays edited by Richard Langlois (1986) and containing, among others, a few chapters written by Austrian economists, including Langlois. The NIE may not have evolved in the direction that Langlois and other Austrians had signaled, but some new institutionalists still have links with Austrian economics. Accordingly, some internal and external observers have referred to an Austrian strand within the NIE (perhaps even North could nowadays be classified

therein, as he has in some senses become closer to the Austrian approach over the years). In contrast, other important reviewers (e.g., Furubotn and Richter, 2005) seem to treat the NIE in such a way as to exclude an Austrian strand. Among the original proponents of the NIE, so did Williamson (1985).

In his characterization of the NIE and its scope, Williamson (2000) distinguishes among four levels of analysis. "The top level is the social embeddedness level. This is where the norms, customs, mores, traditions, etc. are located. … Level 1 is taken as given by most institutional economists." The supposed reason for this is that "[i]nstitutions at this level change very slowly – on the order of centuries or millennia" (p. 596). This would be the terrain of economic historians, sociologists, and other social scientists outside economics. Williamson seems unaware, however, that several economists have been studying informal institutions. This has long been true of the OIE, and it has become increasingly so within the NIE and within mainstream economics. "The second level is referred to as the institutional environment" (Williamson, 2000: p. 598). This includes formal rules such as constitutions, contract laws, and property rights. Only exceptionally will major events (such as civil wars, occupations, etc.) open a window of opportunity for broad reform. "Absent such a window, major changes in the [formal] rules of the game occur on the order of decades or centuries" (p. 598). The third level is that of the institutions of governance. This is what transaction cost economics investigates, focusing on the governance of contractual relations and comparing different governance structures (such as markets, hybrids, firms, bureaus, etc.). Here lies, for example, the issue of vertical integration or, in other words, the make-or-buy decision that was originally explored by Coase. "The possible reorganization of transactions among governance structures is re-examined periodically, on the order of a year to a decade, often at contract renewal or equipment renewal intervals" (Williamson, 2000: p. 599). A large part of the NIE works at levels two and three. When discussing level three, Williamson (2000: p. 599) himself notes that Commons was a precursor of this kind of analysis. Within the OIE, the strand more strongly influenced by Commons has continued this line of research. Finally, the fourth level refers to resource allocation, involving the determination of prices and quantities, and incentive alignment. This "is the level at which neoclassical economics works. Optimality apparatus, often marginal analysis, is employed" (Williamson, 2000: p. 600). In terms of time reference, 'adjustments to prices and output occur more or less continuously' (Williamson, 2000). Williamson's scheme may suggest that at this level institutions do not matter, except for incentives.

Methodologically, the NIE is, on average, much more inclined to mathematical formalization than the OIE. On the other hand, some important new institutionalists, such as Coase, North and Williamson, have not usually built mathematical models (although some of their ideas have been expressed in mathematical terms by others). Nor have the representatives of the Austrian wing of the NIE.

The greater degree of mathematical formalization certainly helps explain why a significant portion of the NIE has been admitted into mainstream economics, but the three authors mentioned in the previous paragraph have, even without mathematically formalizing their ideas, reached the pinnacle of prestige in the profession by winning the Nobel Prize in Economics. So did Elinor Ostrom, who shared the Prize with Williamson and was a member of ISNIE. In other cases, the fact that more traditional neoclassical economics already was part of mainstream economists has helped the extension of the neoclassical apparatus to a range of institutional issues join the mainstream club. In contrast, there are also parts of NIE – especially if we can include an Austrian wing therein – that have remained at the margins of mainstream economics.

The NIE is not defined by a unified political-ideological stance. Several of its proponents criticized the way earlier authors, using neoclassical theory and the notion of market failure, had defended state intervention on the basis of a comparison between a concrete economy and an ideal benchmark deprived of many institutions. The NIE argues instead for a more realist comparative institutional analysis, which may or may not be favorable to an institutional set up with a more active state. Some important authors within the NIE have had links with the Mont Pelerin Society, like Coase and property rights theorists Armen Alchian and Harold Demsetz, and several others are inclined toward a minimal state, but not all new institutionalists are neoliberals.

The Demarcation between the Original and the New Institutional Economics

There are numerous issues about which the OIE and the NIE can be compared and contrasted. In an attempt to differentiate and legitimate their approach, some authors, such as Coase, Langlois, and Williamson, have tried to distinguish the NIE from the OIE by arguing that the latter is nontheoretical or, even worse, antitheoretical. This was not true of Veblen and other early authors, nor is it true in recent decades. For example, the collection of articles originally published in the Journal of Economic Issues and edited by Marc Tool (1988) is intended to provide a comprehensive set of theoretical discussions of several issues that are relevant for the OIE (even if somewhat dated, this compilation is still useful, because of its organization, quality, and comprehensiveness). More recently, another major example is the work of Geoffrey Hodgson, the main and most prolific theorist in the original institutionalist tradition nowadays.

For Hodgson (1998), the crucial demarcation criterion is that the NIE takes the individual as given, for the purposes of economic analysis, while the OIE does not. Other important original institutionalists have defended similar arguments. Dequech (2002), however, maintained that recent developments in the NIE have made the demarcation more complicated. Some proponents of the NIE can be said to have acknowledged and even emphasized what we generically called above the strong influence of institutions on individuals. But what exactly does this strong influence mean?

This can be discussed with the help of the following distinction among types of influence that institutions exert on individual thought and behavior. The cognitive influence of institutions is threefold: informational, practical, and profound. They provide information (in particular about the likely behavior of others), they incorporate practical or tacit knowledge about how to do things, and they influence the way

in which individuals select, organize, and interpret information. The motivational influence of institutions is twofold: simple and profound. The simple variant consists in providing incentives, given the individuals' values, objectives, and obligations. The profound motivational influence is exerted on the values that individuals hold, the objectives they pursue in their instrumental actions, and the obligations they attribute to themselves in their noninstrumental actions. Institutions may also influence the individuals' emotional state, thereby having an emotional influence. Either directly (as rules that give power to individuals occupying certain positions) or through the above-mentioned roles they play, institutions allow individuals to do many things. They thus have an enabling influence. On the other hand, institutions also act as constraints; this is their restrictive influence.

What was called above the strong influence of institutions on individuals can now be argued to include, more specifically, the profound variant of (1) the cognitive and/or of (2) the motivational influences. While arguing that institutions constrain individuals and provide them with information and incentives, one could still see the individual as essentially given in relation to institutions. If, however, one accepts that institutions affect the way in which people select, organize, and interpret information, and/or that institutions influence people's values, objectives, and obligations, then one should acknowledge that institutions partly explain individuals, instead of being completely explained by them. In this case, the individual cannot be the single starting point of institutional theory.

This latter argument goes against what can be called extreme forms of methodological individualism. On the other hand, going beyond the argument that institutions strongly influence people's cognition and motivation, and maintaining that institutions determine them would correspond to an extreme form of methodological collectivism. However, terms like methodological individualism or methodological collectivism have been given a wide array of different meanings. Instead of using these labels, it is better to discuss how a certain approach or work allows or does not allow institutions to have those various types of influence on individuals, and individuals to transform institutions.

Whether the profound variety of the cognitive and motivational influences is highlighted or not is indeed a crucial question that distinguishes some approaches to institutions from others. It does work to distinguish the OIE from a large part of the NIE – but not all the NIE. Eminent authors who are associated with the NIE, such as North (1990, 2005), Greif (2006), and Aoki (2001), have, in their own way and with their own concepts, recognized these profound institutional influences, thus pushing the frontiers of the NIE and, more broadly, of mainstream economics.

This is one among other possible examples that labels like the OIE and the NIE have a limited usefulness.

Other Approaches that Emphasize Institutions

In addition to the OIE and the NIE, there are several other approaches within economics that emphasize institutions. Some of them, like the regulationist school and the economics of conventions (both originated in France), even have major exponents who describe themselves as institutionalists (of a different kind from both the OIE and the NIE). To a lesser extent, this also happens within Post-Keynesian economics, which since its inception in the 1970s has argued that institutions matter (Post-Keynesians who see themselves as institutionalists usually have closer ties to the OIE than to the NIE). The variety of behavioral economics put forward by Herbert Simon has placed special emphasis on organizations and, to a lesser degree, on other institutions. Partly under Simon's influence, so has neo-Schumpeterian economics. Austrian economics – which is not restricted to the Austrian wing of the NIE – has always devoted a great deal of attention to institutions, starting with Carl Menger. A more recent approach, evolutionary game theory, has focused on institutions assuming some sort of bounded rationality. In a sense, we are all institutionalists now.

In the last three or four decades, new institutionalisms have also appeared in other disciplines, like sociology and political science. As Paul DiMaggio (1998) convincingly argues, however, it is better to categorize different works by theoretical orientation than by discipline. DiMaggio distinguishes between three types of new (or neo) institutionalisms. Rational-action new institutionalism "views actors as coherent and strategic, and interests as stable and exogenous." Most of this work "explains the prevalence of economic and political institutions on the basis of problems that these institutions solve for actors who adopt them." Social-constructionist new institutionalism "argues that all the elements of rational-action models – actors, interests, and preferences – are 'socially constructed' and therefore endogenous and variable. … Its proponents emphasize that how pressures to appear legitimate, environmentally imposed uncertainty, and normative schemes embedded in professional training and practice" lead to organizational convergence, not necessarily to greater efficiency. Finally, mediated-conflict new institutionalism focuses "on how state institutions structure and mediate conflict among the interests of groups. … Cross-national policy differences and variation within polities over time are seen as reflecting changes both in the relative power of interests groups and in the openness of political institutions to different forms of political action" (DiMaggio, 1998: pp. 696–697).

A large part of the NIE can be seen as belonging to DiMaggio's rational-action new institutionalism. In contrast, the OIE has a greater degree of proximity to social-constructionist and mediated-conflict institutionalisms. However, classification is not so simple, both within economics, as already argued above, and across disciplines. DiMaggio himself points out that hybrids have emerged, and areas of potential collaboration exist among the three new institutionalisms he identifies. It should be added that outside economics, too, there are approaches that emphasize institutions without being labeled as institutionalist.

Much more dialogue is desirable among the various approaches that study institutions, both within economics and across disciplines. Their languages are varied, and communication is not always easy. Even after suitable translations there will be cases of conflicting ideas. However, there is a great deal of potential similarity or, more frequently and perhaps even

better, compatibility and complementarity between several approaches. Journals like the Journal of Institutional Economics, which is linked to the European Association for Evolutionary Political Economy (EAEPE), help promote an open-minded debate, by publishing contributions from mainstream and nonmainstream economists, as well as noneconomists. In the same vein, also promising is the recently formed World Interdisciplinary Network for Institutional Research (WINIR), which involves scholars from several disciplines and proponents of many different approaches.

This article is a revision of the previous edition article by H. Scherer, A. Quast, volume 16, pp. 10847–10853, © 2001, Elsevier Ltd.

Abstract

This article describes the main olfactory system and the accessory olfactory system (AOS), their receptors and their neural projections to the brain. Both olfactory and vomeronasal systems use seven-transmembrane receptors, which respectively, send nerves to the main and accessory olfactory bulb (AOB). The main olfactory bulb has a number of cell types organized in layers, with the AOB situated in the dorsal posterior region of the olfactory bulb. The AOS sends signals to the amygdala and hypothalamus to stimulate pheromonal effects. Tests used to examine olfactory ability in animals and humans are described as are problems associated with the sense of smell in a number of neurological diseases.

The specific processes that result in the perception of an odorant, although crucial for the survival of most mammalian species other than humans, are yet to be fully understood. This article provides an overview of our current knowledge of the anatomical and functional pathways of the main olfactory system (MOS) as well as those of the accessory olfactory system (AOS) found in most mammals other than humans and some primates. We describe the measurement of olfactory function and discuss the factors, other than disease, that may influence the ability to process olfactory information. We conclude by describing diseases that disrupt our sense of smell; some of these disorders are particular to the olfactory system and others affect the central nervous system, in general.

The Main Olfactory System

The MOS consists of the nasal epithelium, the olfactory bulb, and its direct projections to the olfactory cortex on the base of the frontal lobe and the medial aspect of the temporal lobe. The olfactory epithelium, limited by dorsal aspects of the nasal vault, the septum and the superior and anterior middle turbinate bones, contains the bipolar olfactory receptor neurons (ORNs). The highly ciliated end of each ORN projects into the olfactory mucus where its receptors interact with airborne substances. The other end of the ORNs pass through the cribriform plate and project to networks of neuronal processes in the olfactory bulb called glomeruli; together the axons of the ORNs form the olfactory nerve (cranial nerve one). The olfactory epithelium contains supporting cells as well as basal cells that continuously replace ORNs, each of which only has a lifetime of several weeks (see **Figure 1**). Specialized glia, known as olfactory-ensheathing cells, assist in the process of regeneration of the axons of ORNs. Of clinical interest is the research involving the transplantation of these olfactory-ensheathing cells to stimulate regeneration following spinal cord injury (Franssen et al., 2007).

Linda Buck and Richard Axel received the Nobel Prize in 2004 for their discovery of genes in the mouse that code for G-protein-coupled olfactory receptors (Buck and Axel, 1991). The Nobel web site provides access to Linda Buck's address to the Nobel Society that describes their research and the workings of the olfactory system in some detail. Mice have approximately 1000 OR genes; humans have approximately 350 functional OR genes, each of which codes for a different OR protein (Malnic et al., 2004). Each OR neuron has one specific receptor type only.

As humans are able to identify 3000 odorants or more it is clear that each ORN cannot represent one odorant; rather, it is believed that a combinatorial code is in effect. The findings that a specific odorant may activate more than one ORN and similarly that different odorants may activate the same receptor provide evidence for this hypothesis. Exactly how an odorant activates a receptor is not known as of this writing. The most plausible theory suggests that a stereochemical relationship exists between an odorant and a receptor (or receptors) that initiates the G-protein-mediated cellular cascade resulting in the firing of the olfactory neuron (Buck and Bargmann, 2012).

As well as the G-protein-coupled olfactory sensory neurons, there is a second type of odor receptor neuron in the olfactory epithelium, the 'trace amine-associated receptors (TAARs),' which express a family of GPCR-related Taar genes. Odor receptors expressing Taar genes occur in small numbers throughout the olfactory epithelium in rodents and humans and are responsive to biogenic amines (Pacifico et al., 2012). There are seven different TAAR olfactory receptors (TAAR2–9).

Figure 1 Schematic of the olfactory epithelium as described in the text. The function of the microvilli is not known. From Jacob, T.J.C., 2014. A Tutorial on the Sense of Smell. http://www.cardiff.ac.uk/biosi/staffinfo/jacob/teaching/sensory/olfact1.html (accessed 05.05.14.).

Figure 2 A schematic of the olfactory bulb with connections as described in the text. A tufted cell (not shown) would function similarly to a mitral cell in this diagram. From Jacob, T.J.C., 2014. A Tutorial on the Sense of Smell. http://www.cardiff.ac.uk/biosi/staffinfo/jacob/teaching/sensory/olfact1.html (accessed 05.05.14.).

Three murine TAARs respond to amines found in mouse urine, and one such receptor in mice (the mTAAR5) is responsive to the urine odors of adult male mice, but not to the urine odors of prepubertal males or females. A number of different volatile amine ligands have been found that bind to TAARs. The human TAAR5 is activated by trimethylamine (Wallrabenstein et al., 2013).

The TAAR olfactory sensory neurons project to discrete glomeruli in the dorsal olfactory bulb. Because the TAARs differ genetically from main olfactory receptors, and in their projection patterns to the olfactory bulb and in their axon guidance, they may constitute a distinct olfactory subsystem in the main olfactory epithelium (Johnson et al., 2012). These TAARs may be receptors within the olfactory epithelium that are hardwired to detect social odors such as pheromones or odors that are 'innately aversive' (Dewan et al., 2013)

The olfactory bulb consists of a variety of cell types organized in a number of layers, including the mitral cell, granule cell, and glomerular layers (see **Figure 2**). The glomerulus is spherical in nature and contains the axons of ORNs and dendrites of mitral, tufted, and periglomerular cells (Wachowiak and Shipley, 2006). Each glomerulus generally receives input only from ORNs that express the same receptor. These specific ORNs synapse on one medial and one lateral glomerulus in each olfactory bulb (Ressler et al., 1994). It is not yet clear how the axons of the ORNs arrive at the appropriate glomerulus. Mitral and tufted cells send output directly to the olfactory cortex, which includes such regions as the anterior and posterior cortical nuclei of the amygdala, the olfactory tubercle, and the piriform and entorhinal cortices. The entorhinal cortex sends fibers to the hippocampus, while the piriform cortex provides connections to the orbitofrontal cortex and the hypothalamus (see **Figure 3**). Information from the olfactory bulb output to the cortex does not follow the organizational principles found in the glomeruli. For example, an

Figure 3 Projections of the olfactory bulb to the olfactory cortex. The amygdala also sends direct projections to the hypothalamus.

individual odor does not activate a particular area of the pyriform cortex, rather neurons appear to be activated in a random fashion. Moreover, mitral cell projections from different areas of the olfactory bulb may project to the same area of the piriform cortex.

Cells in the remaining layers of the olfactory bulb are primarily involved in regulating the output of mitral cells. For example, granule cells form dendrodendritic connections with mitral cells. As mitral cells release glutamate and granule cells release GABA, this can result in the unusual situation whereby mitral cells inhibit their own action or the action of other nearby mitral cells. While the function of this process is not clear, it has been suggested that inhibition may act to enhance the signal-to-noise ratio of incoming information by preventing the firing of other neurons (Arevian et al., 2008). The olfactory cortex through its retrograde projections to the bulb may also modulate responses to specific odors depending upon the motivational or physiological state of the individual.

The Accessory Olfactory System

The AOS consists of the vomeronasal organ (VNO), the accessory olfactory bulb (AOB), and its direct projections to the medial amygdala, which, in turn, sends signals to the hypothalamus. Although humans and other higher order primates have vestigial remnants of a VNO, evidence for any functional response remains elusive (Meredith, 2001). The VNO is known primarily for its role in the detection of pheromones. Pheromones are chemicals that produce a species-specific response, resulting in a change in the physiology or behavior of the animal receiving the signal. For example, a pheromone may signal the availability of a mate or result in a sexual or aggressive response. Although primarily a function of the AOS, it has been determined that, in some instances, the MOS also detects pheromones (Keller et al., 2009).

The VNO is a crescent-like tubular structure located bilaterally in the nasal septum at the base of the nasal cavity. Its duct opens into the nasal cavity where it receives nonvolatile chemical signals, frequently found in urine or in glandular excretions. These signals are detected by receptors on apical microvilli of the sensory epithelium that is located on the concave inner surface of the VNO. The stimuli are delivered to the epithelium through fluid produced by vomeronasal glands. Blood vessels associated with the VNO dilate or constrict and create a pumping action that facilitates the delivery process.

Similar to the ORNs, the VNO neurons have seven-transmembrane receptors but, unlike the olfactory epithelium, the VNO has several different types of receptors: V1R, V2R, and FPRs (Formyl peptide receptor-like proteins). They are structurally unlike ORN receptors are coupled with different G-proteins and use different signaling pathways. The V1R and V2R receptors are found in two distinct zones within the VNO. In the mouse, there are about 100 different receptors of both types (Herrada and Dulac, 1997). The role of FPRs in the VNO is not yet understood although it has been suggested that they may be involved in the sensing of pathogens. Like the relationship of ORNs to glomeruli, VNO receptors of the same type also converge upon mitral cells in specific glomeruli in the AOB.

The AOB itself is embedded in the dorsal posterior area of the main olfactory bulb. It sends signals directly to the medial amygdala, from there to the bed nucleus of the stria terminalis and on to the hypothalamus. It is the action of the hypothalamus that is responsible for some very specific responses to chemical stimuli. In mice, among the most well-known pheromonal effects other than the initiation of mating behaviors and aggression are the phenomena of pregnancy block (Bruce effect), puberty acceleration (Vandenbergh effect), and estrous cycle synchronicity (Whitten effect). Pregnancy block results when a female mouse aborts its pregnancy if it encounters the odor of the nonstud male prior to embryo implantation. The Vandenbergh effect refers to the acceleration of puberty in female mice following the exposure to the odors of an adult male conspecific. The Whitten effect occurs when female mice that are housed in unisexual groups begin to cycle in synchrony when an adult male is introduced to their cage. The chemical constituents of the latter pheromones have been identified and are found in urine. Debate continues regarding the role of other compounds found in urine such as major urinary proteins and major histocompatibility complex (MHC) fragments both of which it has been argued are involved in mate choice and kin and individual recognition.

The discovery that synchronization of the menstrual cycle occurs in women living in group housing (McClintock effect) gave rise to the suggestion that humans are also influenced by chemical stimuli. Follow-up studies by McClintock and others have demonstrated that humans undoubtedly react both consciously and unconsciously to the smells of other individuals. For example, females prefer (or at least find less aversive) the axillary odors of males with a MHC that is different than their own (Wedekind and Penn, 2000). Having a male with different MHC genes as a partner would be of considerable value as it would create greater immunocompetence in resulting offspring. Although it seems clear that humans do not have a functional AOS and that the term 'pheromone' may not be an appropriate designation for such a stimulus, this does not preclude our ability to detect and respond to the odors of another individual (Wyatt, 2014). The MOS includes projections to the limbic system that could mediate both physiological and psychological responses to an odorant.

Assessing Olfactory Function

A number of well-validated tests with normative data collected have been developed to assess olfactory ability in humans. The University of Pennsylvania Smell Identification Test or UPSIT, which can be self-administered and is available in multiple languages is perhaps the most well-known. It consists of 40 different 'scratch and sniff' squares each encapsulating a common odor such as cinnamon, peanut butter, cut grass, or motor oil. It may be used to assess detection, identification, and the ability to discriminate between or remember odors (Doty, 2006).

To measure absolute olfactory threshold, i.e., the lowest concentration of an odorant that can be detected, odors are usually presented sequentially from high to low concentrations (descending limits) or from low to high concentrations (ascending limits). Organic compounds such as phenyl-ethyl

alcohol or n-amyl acetate are generally used in such tests. For this procedure, a well-controlled odor delivery system is essential if accurate results are to be obtained. Electrophysiological techniques may also be used to assess olfactory function. Both the examination of olfactory event-related potentials and responses to an electroolfactogram, which detects electrical changes in the olfactory epithelium in response to an odor stimulus, are useful to assess individuals who are unable to provide reliable responses to less invasive tests. With the advent of structural and functional imaging techniques, the brain structures involved in olfactory information processing may also be examined. For example, an fMRI study has found that the orbital frontal cortex is activated during the judgment of an odor's hedonic value (Katata et al., 2009)

The ability to detect odors is influenced by a number of factors including age, gender, and hormonal status. It has been well established that females have a lower detection threshold than males. Moreover, olfactory acuity in females is more acute during the ovulatory phase of the menstrual cycle (Navarrette-Palacios et al., 2003). The ability of humans to detect odors also declines with normal aging and as a result of disease (see Section Olfactory Dysfunction and Disease). Specific anosmias also exist in a small fraction of the population. The most well-known example being the inability to detect 5-α-androst-16-en-3-one (androstenone) a boar pheromone and a compound found in urine and axillary sweat in humans (Wysocki et al., 1989). Mutations in specific odor receptors are likely to be the origin of specific anosmias.

A variety of paradigms are used to assess olfactory ability in nonhuman mammals. These include the buried food test and the habituation–dishabituation task. In the former paradigm, a food-restricted animal is required to find a food particle by digging in a substrate such as sand or bedding material. In the latter test, the animal's sniffing response to successive presentations of an odor is recorded. Successive presentation of the same odor will result in a decrease in investigation. When a second stimulus is presented, the previously habituated response, i.e., sniffing, will reoccur if the animal can discriminate between the different stimuli. Neither of these procedures is particularly valid or reliable as a negative result is impossible to interpret. If the animal does not detect a stimulus or does not discriminate between two stimuli, this failure could reflect a lack of interest or motivation rather than a lack of ability. Also, sniffing behavior, which is used to measure a response, is not often defined and this makes it difficult to compare results between different studies. Using a conditioned digging task or an operant olfactometer avoids the latter problems and has been demonstrated to provide more reliable results. Animals that have not dug for food or sniffed at a stimulus have been found to detect odors when assessed in these more rigorously designed tasks. The advantages and disadvantages of the various methods have been described by Schellinck and Slotnick (2013).

A comparison of olfactory ability in human and nonhuman mammals demonstrates the exceptional degree of odor sensitivity in some species. For example, although humans have been shown to detect an odorant in parts per billion, both dogs and rodents have been found to detect odors in parts per trillion. These differences may be accounted for in several ways: these animals may have longer cilia with more receptors; they possess a greater number of functional receptor genes and have a larger area of epithelium. Moreover, dogs unlike humans, have two separate airflows, one for respiration and one for olfaction, which provides more air for analysis (Craven et al., 2010). Also, they and other animals may make use of their AOS to process signals associated with bodily odors.

The extraordinary ability of dogs and rodents to detect odors has led to the use of these animals in a number of useful capacities. Tracker dogs have long been employed to search for lost or suspect individuals as well as to detect explosive devices or contraband substances. A species of rat is now replacing dogs in some instances to assist their trainers to find landmines in war-torn countries such as Mozambique and Cambodia and to detect explosives and drugs in Holland. Mice have also been trained to sniff out bombs in Israel. Currently, research is underway to determine if dogs can reliably detect specific volatile organic compounds or 'odors of disease' in the breath of individuals with Type 1 diabetes and cancers of the bladder, lung, and breast, in particular.

Olfactory Dysfunction and Disease

Problems associated with the sense of smell have been categorized according to the degree and type of dysfunction (**Table 1**). At least 70% of a person's sense of flavor is derived from olfactory cues such that anosmia results in food being experienced only as sweet, sour, salty, bitter, or umami. Despite the psychological and physiological deprivation that this situation created for its sufferers, clinicians showed little interest in olfactory dysfunction. With the discovery that the sense of

Table 1 Disorders of olfaction and common causes

Anosmia: Total absence of the sense of smell; this may be a result of the shearing of the olfactory nerve following head trauma; viral infections, toxins, or a genetic abnormality leading to lack of epithelium or receptor proteins.
Dysosmia: Partial impairment of the sense of smell; this is a general term and most disorders are more precisely described using the terms below.
Hyposmia: A Decrease in olfactory acuity; it may be associated with allergies, infection, head trauma, Alzheimer's disease, or Parkinson's disease.
Hyperosmia: An increase in olfactory acuity; this may be a result of a genetic polymorphism resulting in increased sensitivity to a particular odor (e.g., isovaleric acid) or from benzodiazepine withdrawal syndrome.
Parosmia: Smelling a substance other than the one that is present; the affected individual knows that their interpretation is incorrect. It may be caused by damage to ORNs as a result of infection but has also been found in patients with Parkinson's disease. Most commonly odors are identified as rotten or like feces. This is called cacosmia.
Phantosmia: A olfactory hallucination in which the individual believes a smell is present when it is not; it may be a result of psychoses but also experienced prior to an epileptic seizure or a migraine.
Pseudosmia: Misinterpretation of a real olfactory impression sometimes found in individuals with psychoses.

ORN, olfactory receptor neuron.

smell is altered in several neurological diseases, this consideration changed. Hyposmia or anosmia is one of the early signs of Parkinson's disease (PD) and occurs prior to motor symptoms; Individuals with Alzheimer's disease (AD) have deficits in both discrimination and identification of odors with detection becoming more of a problem in the later stages of the disease. Low scores on the UPSIT have also been found in patients with multiple sclerosis and motor neuron disease. For individuals with PD and AD, a greater understanding of olfactory dysfunction may create an early biomarker for these illnesses.

Abstract

The iron law of oligarchy refers to a provocative and very influential theory posited by German social theorist, Robert Michels. In his seminal analysis of the German Social Democratic Party in 1911, Michels argued that all organizations – no matter how democratic their original intentions – eventually come to be ruled by a powerful entrenched minority that, when necessary, will act illegitimately to squelch internal opposition and divert the organization's goals in order to maintain its power. This article summarizes Michels' argument, reviews the theoretical debates it has provoked, outlines the findings of the empirical research evaluating his claims, and discusses some of the methodological difficulties that have plagued this inquiry.

In 1911, Robert Michels summarized his analysis of the German Social Democratic Party with the now-famous phrase "Whoever says organization, says oligarchy" (Michels, 1962: p. 365). Though a dedicated socialist at the time, Michels nevertheless concluded that in modern society, both socialism and democracy were structurally impossible – that the very principle of organization made oligarchy the inevitable result of any organized collective endeavor. This conclusion – known as the 'iron law of oligarchy' – has probably been the most influential and widely debated claim in the study of organizations. Despite over a century of empirical research in a range of subfields in political science and sociology, however, there is still no consensus about whether or under what conditions Michels' claim holds true. In what follows, I will first review Michels' original argument about the development of oligarchy and its consequences, then outline the impact of the iron law on the study of political parties, social movements and other voluntary associations, and workers' collectives.

Michels' original argument can be distilled into three basic claims:

1. *Bureaucracy happens*. Large-scale organizations in modern society will tend to develop a rational-bureaucratic structure (i.e., a system of procedural formality, jurisdictional specialization, and hierarchical authority). Bureaucracy arises due to a structural imperative that affects every organization, but increases as the organization grows: effectiveness requires administrative efficiency, which in turn requires a complex and hierarchical division of labor.
2. *If bureaucracy happens, power rises*. The hierarchical delegation of authority inherent in a rational-bureaucratic structure necessarily concentrates power in the hands of a minority. As this minority becomes intimately familiar with the day-to-day operations of the organization, it develops into a professional leadership with a monopoly of skills, knowledge, and resources. This state of affairs, aided by the supposed 'incompetence of the masses,' makes the leadership indispensable, as the rank and file come to rely on them for their expertise.
3. *If power rises, power corrupts*. Once power is concentrated in the hands of a minority, the leadership develops an interest in maintaining the status and perquisites of its position. Driven by a supposedly inherent 'desire to dominate,' the minority, having once attained this position, will do whatever is necessary to preserve its own power – even when that means going against the interests of the membership – and will use undemocratic means to stifle any internal opposition which it interprets as a threat to its authority. The organization becomes an end in itself, and as a result, the leadership becomes susceptible to co-optation and to the displacement of the membership's original goals for the sake of organizational maintenance.

Critics have debated and challenged Michels on each of these three claims. The earliest and least frequent line of attack came from an orthodox Marxist position that challenged the second step of Michels' argument, the claim that bureaucracy necessarily concentrates power. Scholars taking this line (e.g., Bukharin, 1925; Hook, 1933) argue that because power is based in the ownership of property, if bureaucrats exercised authority without owning the means of production (as they claimed is the case in a socialist state), the bureaucratic leadership would have no real power to either defend or abuse, and thus could not be considered oligarchic. This line of argument has been soundly critiqued by scholars of power who hold that people who *control* resources – i.e., who have administrative authority – can have at least as much impact on people's lives by monopolizing decision-making processes as those who *own* resources (see e.g., Dahrendorf, 1959). In other words, what makes a group oligarchic is their power to control the processes by which decisions are made and implemented, regardless of what allows them to wield that power.

By the 1950s and 1960s, a second set of arguments began to appear, this time focusing on the third step in Michels' argument. Taking a pluralist perspective, these critics accepted that bureaucracy happens and that in a bureaucracy, power rises, but they rejected the assertion that power must necessarily corrupt and posited various ways in which a powerful minority might be held accountable to the majority it is meant to represent (Edelstein, 1967; Gouldner, 1965; Lipset et al., 1956; Schumpeter, 1950). Others concerned with accountability have focused on the process of goal displacement, i.e., the tendency of entrenched leaderships to abandon the membership's original goals in favor of those that ensure organizational survival and growth (Barnes, 1987; Gusfield, 1955; Merton, 1957; Selznick, 1949; Sills, 1957).

In the 1980s, a new critique emerged that challenged the first step of Michels' argument – the underlying premise that organizations must necessarily develop a bureaucratic structure in order to be effective (Breines, 1980; Rothschild and Whitt, 1986). Even though his primary referent, the German Social Democratic Party, was in fact a large-scale bureaucratic organization, Michels explicitly stated that he was talking about *all* types of nominally democratic organizations: "The formation of oligarchies within *various forms of democracy* is the outcome of organic necessity, and consequently affects *every* organization …" (Michels, 1962: p. 366, emphasis added). And while Michels assumed that bureaucracy was the only sustainable form of organization, he nevertheless acknowledged that *if* bureaucracy could be avoided, then theoretically, so could oligarchy. Prior to the 1970s, however, empirical research had been restricted to large-scale, bureaucratically structured membership organizations. Critics felt that the wave of workers' collectives, communes, cooperatives, and political groups born of the New Left's commitment to participatory democracy could pose a serious challenge to the iron law, yet because nonbureaucratic organizations were being perceived as *dis*organized rather than *differently* organized, these potentially exceptional cases were not being acknowledged.

In any case, more attention is being paid to the applicability of the iron law in nonbureaucratic settings, in part because these groups clearly struggle with the problem of oligarchy, just as bureaucratic organizations do, but also because, contrary to Weber's prediction, nonbureaucratic organizations have become an increasingly prevalent feature of the modern institutional landscape. These structures are widely used in social movements, workers' cooperatives, protest/cultural encampments (e.g., Burning Man, Occupy, the Brazilian Landless Movement), communes, neighborhood associations, Internet campaigns, and forums for local self-governance. The impulse is even apparent in large corporations that have begun to adopt less hierarchical, more participatory team-based structures (Polletta, 2014; Rothschild, 2000).

Having outlined the most common avenues by which critics have evaluated the iron law, we now turn to a brief substantive review of their findings.

Conditions Affecting Oligarchy and/or Goal Displacement

Building on categorizations laid out by Zald and Ash (1966) and Lipset et al. (1956), I will organize the literature addressing Michels' thesis by the *types* of variables that have been found to contribute to the rise of oligarchy or its absence. I will incorporate findings from studies done in the whole range of organizational settings, including social movement organizations, unions, political parties, voluntary associations, local governing bodies, workers' cooperatives, and for-profit businesses. Reviews of the literature usually list findings separately for each of these settings, because they correspond to the disciplinary subfields that have been influenced the most by Michels' thesis (e.g., Ansell, 2001). While that approach is useful for those looking to focus on a particular subfield, however, one of the most important things we have learned from a century of research on oligarchy is that the *purpose* of the organization matters far less than characteristics related to how it is structured, the nature of its membership, and the environmental context in which it operates – factors that may be shared by a host of organizations with dissimilar goals and purposes. I highlight these factors in order to provide a better overall sense of where we stand in the study of oligarchy and what we have left to accomplish.

Forms of Authority: Bureaucracy, Collectivist Democracy, and Noncharismatic Personalism

Michels assumed, following his friend and mentor Max Weber, that traditional and charismatic forms of authority would increasingly be supplanted by rational-legal authority in modern society, and that rational-legal authority, expressed in bureaucracy, would give rise to oligarchy. However, two other forms of authority – neither of which were included in Weber's typology – have been hypothesized to affect the development of oligarchy. For example, in their study of three ideologically diverse political parties in Germany, France, and Russia, Ansell and Fish (1999) found that the basis of a leadership's indispensability depends not on their bureaucratic control of resources and information, but on the form of authority that prevails in the party, which in turn depends upon the types of cleavage structures that are most salient. In parties where both territorial and ideological cleavages are highly salient, they argued that a "non-charismatic personalist" form of authority develops, and the leadership's indispensability is based on its ability to resolve conflicts between factions. Such parties did develop an oligarchy, but via a different pathway than Michels laid out.

As mentioned above, another form of authority, collectivist democracy, may have the potential to prevent oligarchy altogether. Rothschild and Whitt examined this possibility in their study of five workers' cooperatives in the 1970s. One of their key findings was that having a "provisional orientation" which they define as the "sentiment that all operations and programs in an organization ought to be tentative" (1986: p. 83), militates against oligarchization. At the other extreme are those who hold that the lack of formal hierarchy makes collectivist organizations *more*, not less, susceptible to oligarchic control (Freeman, 1972; Staggenborg, 1988). Jo Freeman, for example, argued that the lack of formal structure and routinized procedures in collectivist organizations simply masks the rule of *informal* oligarchs, producing a 'tyranny of structurelessness.' Most scholars, however, have found that a collectivist structure is neither immune to oligarchy nor especially susceptible to it. In fact, research on organizations of all types suggests that while the vast majority do eventually succumb to oligarchy, whether, how, and how quickly it develops are contingent on a range of structural, environmental, and cultural factors.

Structural Factors

Certain characteristics of an organization's structure and practices have been found to affect the development of oligarchic rule. At least four such factors are likely to affect both formal and informal organizations. For one, scholars have generally supported Michels' claim that larger size makes oligarchy more likely (Johnson and Whyte, 1982; Rothschild and Whitt, 1986),

although some studies have found either no correlation or a negative correlation with size (Getz, 1998; Rosner, 1998). A second factor that could affect all organizations is professionalization. As with size, there is disagreement on the effect of this factor, with some supporting Michels' prediction that it facilitates oligarchization (Piven and Cloward, 1977; Zald and Ash, 1966) and others (e.g., Staggenborg, 1988) arguing that formal organizations with professional leaderships do not have to become oligarchic – that the routinized procedures make it harder for individuals to gain disproportionate power. Third, some kind of mechanism that assures the broad diffusion of knowledge, information, and technological skills among the membership is necessary for maximal participation and to keep elites from forming and/or becoming oligarchic (Katovich et al., 1981; Lipset et al., 1956; Rothschild and Whitt, 1986). Lastly, there needs to be some kind of structured mechanism to protect people from reprisals when they dissent or challenge the leadership (Bernstein, 1982; Lipset et al., 1956).

Other structural factors have been posited as specifically relevant in either bureaucratic or collectivist settings. In bureaucratic organizations, for example, the presence of factions and subgroups that vie for leadership helps to assure leadership accountability and/or turnover (Lipset et al., 1956; Zald and Ash, 1966). Similarly, Baiocchi (2005) found in his study of the participatory budgeting forums in Porto Alegre that in districts where popular councils and activist networks existed outside of the official forums, the process engendered more trust and participation and was less prone to debilitating conflict. Research on collectivist organizations has generated less consensus about which structured practices (stable norms) help groups to prevent/contain informal domination. Freeman (1972) specifically argues that a more structured division of labor (including a more fixed committee structure, the rotation of functionally important tasks, and a broad diffusion of information among members) as well as a more structured decision-making process are both necessary to keep informal elites from dominating the group. There is broad agreement about access to information and the rotation of tasks, but several scholars have found that a decision-making process that is too structured alienates the uninitiated and generates an in-group that is able to manipulate the process in its favor (Juris, 2008; Leach, 2013).

Organizational Environment

External factors having to do with the institutional context within which the organization operates can have an enormous effect on its ability to maintain a democratic distribution of power. A host of studies on social movement organizations have noted the impact of funding sources in this regard, as elite beneficiaries often make their contributions contingent upon the use of more conventional tactics, more formal organizational structures, and/or the ability to demonstrate high levels of operational efficiency, all of which push the organization in the direction of professionalization, oligarchization, and conservatism (Clemens, 1993; Ferree and Martin, 1995; Piven and Cloward, 1977; Rothschild and Whitt, 1986; Staggenborg, 1988; Voss and Sherman, 2000). The Mondragon complex in Spain, with over 160 workers' cooperatives and 23 000 members, successfully addressed this problem by creating its own banking system to fund new start-ups (Johnson and Whyte, 1982). Other scholars point to inter-organizational relationships and/or the organization's position in a broader organizational network as key, whereby the organization must either have a high degree of autonomy or be densely networked with other democratically inclined organizations to improve its chances of remaining democratic (Fisher, 1994; Lipset et al., 1956; Zald and Ash, 1966).

For political parties, electoral procedures, the conventions and regulations related to the governing process, and the demographics of potential members/voters have all been found to constrain a party's ability to remain internally democratic (Markovits and Gorski, 1993; Swerdlow, 1973; Zald and Ash, 1966). Similarly, research on workers' cooperatives has found that economic competition and the nature of markets can force organizations to sacrifice more democratic practices for the sake of efficiency, opening the door for oligarchy (Getz, 1998; Rosner, 1998). Breines' (1980) analysis of the collapse of Students for a Democratic Society – the leading organization of the student movement in the 1960s – argued that government repression was a major factor that fed the polarization, radicalization, and turn to militancy in the group, ultimately contributing to their rejection of participatory democracy and allowing an oligarchic minority to seize control of the organization.

Lastly, two recent studies of political parties present models combining external structural factors and internal cultural variables to explain the dynamics of power. In his study of left-libertarian parties, Kitschelt (1989) portrays the Michelsian dilemma as a conflict between two party logics – a logic of constituency representation, which works against oligarchy, and a logic of electoral competition, which hastens it. Which of these logics dominates depends on the relative strength of subgroups he labels ideologues, lobbyists, and pragmatists. This, in turn, is determined by the 'political opportunity structure,' which includes such external factors as the degree to which the libertarian left is mobilized, how existing elites respond to the entry of a new party into the political system, the competitive position of the party in relation to others, and the number of active left-libertarian movements. Rohrschneider (1994) similarly points to changing cleavage structures in the European party system – specifically, the emergence of the 'New Politics' orientation – to argue that New Politics proponents in the 52 established parties he studied were more likely to side with local constituencies than with leadership on contested party decisions. He argued that this was due to their socialist convictions, not party structure, and that the presence of this ideology undermines Michels' two classist psychological assumptions (that the masses are incompetent and that leaders will always have a will to dominate), thus potentially weakening Michels' argument.

Cultural Factors

Beyond these structural features, some scholars have pointed to aspects of organizational *culture* that may be necessary to avoid oligarchy. Such factors have been especially prevalent in research on collectivist organizations. For example, particular kinds of ideology have been found to enhance the effectiveness and longevity of collectivist groups, such as an ethic of

cooperation and egalitarianism (Iannello, 1992; Leviatan, 1998), an antinuclear ideology (Downey, 1986), religious ideologies such as Quakerism, Christian pacifism, or paganism (Epstein, 1991; Leach, 1998), and anarchist ideology (Day, 2005; Epstein, 1991, 2001; Graeber, 2009; Lyons, 1988). And, of course, feminism has been one of the driving forces behind experimentation with participatory forms of organization (e.g., Ferguson, 1984; Ferree and Martin, 1995; Harris and King, 1989). Other cultural factors found to contribute to the longevity of democratically inclined organizations more generally are an organizational culture that encourages dissent and conflict (Epstein, 1991; Rothschild and Leach, 2006), a homogeneous membership (Johnson and Whyte, 1982; Lipset et al., 1956; Rothschild and Whitt, 1986), status differences within the group (Lipset et al., 1956; Polletta, 2002), a culture of mutual self-criticism (Rothschild and Whitt, 1986), the social status of the members in the larger society (Clemens, 1993; Lipset et al., 1956), and the development of new forms of association within the larger decision-making units, such as affinity groups, consciousness-raising groups, pacifist 'disciplines,' or residential clusters (Polletta, 2002). Finally, some have suggested that groups with an instrumental logic of action are more susceptible to oligarchy than more expressive, value-rational groups (Koopmans, 1995; Kriesi, 1996), although oligarchy has certainly been found in expressive groups as well (Schmidt, 1973).

Methodological Issues and Emerging Directions

As is evident from the discussion so far, there is still much disputed terrain in the debate over the iron law. While it has provoked research for over a century now, questions about whether oligarchy is truly inevitable and the conditions under which it might be avoided remain unresolved. One major reason for this is that there has been no agreed-upon operational definition of what constitutes oligarchy across organizational forms (Leach, 2005). Different measures have been used from one context to the next – often without the choice being explicitly stated or defended. As Schmidt noted in 1973, "Since Plato and Aristotle, most writers who discuss oligarchy fail to define the concept, apparently because they assume the word is understood in the light of its Greek etymology (the rule of a few). Michels also fails to offer a formal definition …" (1973: p. 10).

Etymologically, oligarchy means 'the rule of the few.' The simplicity of this definition, however, belies the host of complex issues that arise in any attempt to empirically assess whether or not an oligarchy exists. For example, what, exactly, do we mean by 'rule'? What must 'the few' do in order to be considered oligarchic? Must they hold formal office or can they work behind the scenes? Is it only oligarchic when a minority is coercive and actively suppresses dissent or is a persuasive minority that gets people to go along with them out of respect for their competence or charismatic appeal also oligarchic? Is there a difference between 'ruling' and 'leading'? If so, is it the exercise of 'power' as opposed to 'influence' that differentiates the two? Or are power and influence both commodities that may be employed by democrats and oligarchs alike? And lastly, is it simply having a certain *amount* of power and/or influence that makes a minority oligarchic (in which case, how much is necessary and how can it be measured?), or does it depend on how the minority *uses* its power/influence that determines whether they have crossed the threshold into oligarchy?

Though definitions of oligarchy are often left implicit, two general tendencies are discernible in the literature. The most common approach has been to treat oligarchy as a feature of the formal authority structure (Lipset, 1952; Lipset et al., 1956; Michels, 1962; Schmidt, 1973; Stone, 1972). Lipset, Trow, and Coleman, for example, characterize oligarchy as a one-party political system where "one group, which controls the administration, usually retains power indefinitely, rarely faces organized opposition, and when faced with such opposition often resorts to undemocratic procedures to eliminate it" (1956: p. 3). This implies that the presence of organized opposition in a two-party system is a sufficient safeguard against oligarchic tendencies.

The problem with this definition is twofold: first, that it ignores the possibility of an oligarchy behind the scenes wielding *informal* power – that is, that a powerful economic or cultural elite could wield oligarchic influence without holding political office (Domhoff, 2014; Mills, 1956); and secondly, that it only works in bureaucratic organizations. If a minority has to have formal authority to be oligarchic, that would mean that collectivist organizations are *never* oligarchic, since no one has formal authority over anyone else. But such a claim flies in the face of a host of ethnographic research, not to mention common sense.

A second tendency has been to effectively equate oligarchy with goal displacement. While it is of course interesting to ask under what conditions organizations that start out with radical goals become more conservative over time – which often occurs as a consequence of oligarchization – asking why an organization changes its goals is not the same thing as asking how many people are ruling it. One cannot assume that just because an organization still has radical goals that it is therefore democratic; nor does a change in goals necessarily mean that an oligarchy imposed the decision. Oligarchies are not always conservative and, more importantly, radical organizations are not always democratic – which was precisely Michels' point about the Social Democratic Party. The direction of goal displacement, when it happens as a result of oligarchy, is generally dictated by the need for external support. Michels' argument was that where external support (in the form of votes or memberships or funding) is necessary for an oligarchic leadership to maintain its power, it will shift the organization's goals in whatever direction is most likely to attract that support.

Confusing bureaucratic conservatism with oligarchy and thereby equating radicalism with democracy is also problematic because it elides the fundamental concern underlying Michels' analysis: the question of how effective parliamentary strategies can be for realizing revolutionary goals. Michels' study of the German Social Democratic Party was largely a critique of the vanguardist strategy embraced by the parliamentary socialists of his day, who, in claiming to represent the emancipatory interests of 'the masses,' felt justified in repressing dissent within their own ranks. Debate over this question has been an especially prominent feature of leftist politics over the last half-century, underlying the New Left's embrace of participatory democracy and the extra-parliamentary stance of

many of the so-called New Social Movements in the postwar era (Breines, 1980, 1982; Epstein, 1991; Katsiaficas, 1997), and playing a central role in the factionalization of the German Green Party (Markovits and Gorski, 1993). If we imagine that all it takes to avoid oligarchy is to remain committed to a radical agenda, no matter how undemocratic the means used by 'revolutionary' leadership might be, we bypass the question at the very heart of Michels' work and indeed, at the very heart of much of activist history since then.

Instead of reducing oligarchy to a particular kind of formal authority structure or conflating it with a conservative policy orientation, it is more accurate to see it as a particular *distribution of power*, which may take the form of either formal authority or informal influence, and which may have a number of bases (e.g., economic, social, informational, or political). Elsewhere, I have proposed a formal definition of oligarchy as "a concentration of entrenched illegitimate authority and/or influence, such that *de facto* what that minority wants is generally what comes to pass, even when it goes against the wishes (whether actively or passively expressed) of the majority" (Leach, 2005: p. 329). This definition focuses on the decision-making process as the focal point for the contestation of power, and requires that, at least in decisions that it perceives could threaten its control, a minority must successfully impose its will through the illegitimate exercise of power, and against resistance, for the organization to qualify as oligarchic. It also notably leaves open the possibility that *any* organization – whether bureaucratic or nonbureaucratic – could potentially either succumb to oligarchy or resist it. In short, it is meant to provide a common measuring stick by which all three of Michels' claims (that bureaucracy is necessary, that it necessarily concentrates power, and that concentrated power necessarily corrupts) can be subjected to empirical disputation, regardless of the organizational setting. Recent studies have begun to use this definitional approach (Diefenbach, 2013; Toplak, 2011). It remains to be seen what progress it may facilitate.

Whatever approach we take, however, it is clear that Michels' groundbreaking work will continue to generate insights into the dynamics of power in organizations of all kinds. But the reach of his legacy goes far beyond the field of organizational studies. In fact, answering the questions Michels raises is key to unraveling perennial issues about larger processes of social change, such as whether grassroots and culturalist strategies for social change can be effective, whether working within the context of large-scale bureaucratic institutions can lead to lasting emancipatory change or if that would require the use of nonhierarchical processes, and whether we should continue to have faith in Tocqueville's argument about voluntary associations in civil society being vehicles for empowerment and democratization. One thing is clear: if, as advocates of participatory democracy have long held, grassroots democratic organizations are to be the breeding ground for an informed and active citizenry in a democratic society, then we will have to get better at breaking the iron law of oligarchy.

Abstract

One of the founding figures in the economic discipline of 'Public Choice,' Mancur Olson developed the logic of how a group provides itself with nonrival, nonexcludable, public goods. Because individual rationality leads every member of a group to free riding behavior, the result of individual rationality is not the group rational outcome. His early writings established the nature of individually rational voluntary provision group equilibrium, described its characteristics, and identified its sweeping scope.

These early insights led to deepened understanding of the role of incentives in political organization and choice. Thus, a major impact of his work was to bring economic logic to bear on the analysis of political behavior, and this led to widespread utilization of economic methods in political science and other studies of nonmarket choice. Examples include interactions among countries in environmental, political, military, or economic alliances, and formulation of important concepts for understanding the success/failure of societies in governing themselves and in achieving economic prosperity.

Such concepts include (1) 'distributional coalitions' that fashion transfers to themselves from the society at large while degrading the economic performance of the whole; (2) a political group's 'encompassing interest' or stake in the overall economic health of its society, which limits the economic inefficiency it causes; or (3) 'demasclerosis,' the opportunity that social stability affords for the buildup of inefficiency causing special interests.

Biography

The son of Norwegian immigrants to the United States, Mancur Olson was born in Grand Forks, North Dakota, USA, on 22 January 1932, and raised near there on a farm. He died on 19 February 1998 at College Park, Maryland, USA. He studied economics at North Dakota State University, Oxford University, and Harvard University. He spent the greatest fraction of his career as an economics professor at the University of Maryland, USA, but before this, he undertook teaching assignments at the US Air Force Academy and Princeton University, and service in the US Department of Health Education and Welfare. Influential in professional associations, he had been President of the US Southern Economic Association, US Eastern Economic Association, Public Choice Society, and Vice President of the American Economic Association. He was a Fellow of the American Academy of Arts and Sciences, an Honorary Fellow of University College, Oxford, and recipient of many other honors and awards. At the time of his death, he was principal investigator and director of a US Government-sponsored development aid/research project with offices in 30 countries, and an ambitious agenda to bring the benefits of his life's work to the design and reform of the institutions of governance throughout the developing and former communist countries of the world.

Antecedents to Public/Collective Choice

One of the founders of Public or Collective Choice as a subdiscipline and movement within economics, Olson devoted his intellectual life to the analysis of collective action. Early, as a student he intuited that the then standard paradigm as to how people interacted economically with each other was seriously incomplete. In the traditional model, it was argued explicitly or implicitly that economic interaction while widespread and diverse, was normally mediated by prices and markets between otherwise isolated and independent agents. The first founding principle of 'Public Choice' and a concern that permeates Olson's life work is recognition that people exchange, produce, consume, and share many goods, in many environments that are not at all mediated by markets and prices, yet the behavior and analysis thereof is unquestionably 'economic.' Typically, in these environments, people belong to identifiable groups and their interaction partakes of their group identity in a manner not conveyed by Adam Smith's butcher or baker. This raises to paramount importance questions of how people and organizations that belong to a group do and should act to achieve their goals.

Oligopoly

Central to the Public Choice nexus is how the size of a group influences the behavior of its individual members and thus aggregate outcome. Other features of group membership such as homogeneity or diversity are also important but size was the first aspect to seize Olson's attention. With respect to industrial behavior, the question of how small numbers of firms would behave had occupied economists' attention for a generation by the time Olson became a student. Still earlier, the pricing, output, employment, and other profit-maximizing behaviors of a single, monopolistic, firm had been successfully analyzed as had those of a market consisting of a large number of atomistic competitive firms (Marshall, 1890). And by the time Olson arrived at Harvard in 1957, for the case of small numbers of firms in an industry, theories of oligopoly interaction (Cournot, 1897; Robinson, 1933; Chamberlin, 1933) had emerged, which demonstrated that in pursuing rational profit maximization for themselves individual suppliers would fail to achieve maximum profits for their industry – their group – as a whole. The reason for this is a lack of coordination: oligopolists fail to anticipate and include in their decision calculus the effects their narrow profit-making decisions have on the profits of other firms. In fact, it would be individually irrational for any single firm to include such external benefits in its

decision calculus since the individual firm could gain more by free riding off the efforts of other firms. A similar coordination failure motivated the fast developing field of Game Theory, which provided a rigorous framework for analysis of oligopolistic behavior. Actually Olson's mentor at Harvard (E. Chamberlin) had been one of the leaders in the evolving understanding of oligopoly with his introduction of the idea of 'monopolistic competition.' Here, individual firms in an industry resemble monopolists in that they recognize their supply decisions will influence the price they can obtain. At the same time, their industry is competitive, in a sense, because the price actually charged by any one firm influences the price–supply opportunities of every other firm.

Public Goods

Parallel with economists' study of producer oligopoly, discoveries preceding Olson showed that provision of some types of goods to consumers could lead to similar failures of coordination (Samuelson, 1954). 'Public goods' or 'collective goods' are such that once available to any member of a specified group, the same quantity and quality is equally available to every other member at no extra cost: this is because such goods are not used up when enjoyed and if available to any consumer cannot be excluded from any other group member. Early examples included the lighthouse beacon, which warns all ships (nonexcludable), and whose utilization by one ship in no way reduces its availability to other ships (nonrival). More contemporary examples include protection of pollution-free environments, provision of national defense, preservation of natural species, establishment of political freedoms, provision of property right guaranteed by an impartial and universal police/judiciary, and maintenance of government by rule law. These all should be understood to be economic 'goods' broadly speaking and all display the property that their enjoyment by one person in no way diminishes their availability to others to enjoy. But if every member of a group enjoys a good irrespective of who supplies it, no one acting voluntarily will provide the good – at least no one will provide a sufficient amount of it. Instead, all will have an interest in seeing others pay the supply costs while they enjoy the benefit so produced without making any cost contribution themselves. Every individual, that is, has good reason to free ride – in whole or in part – on the provisions of others. One, therefore, should anticipate that for the provision of such public goods, free markets based on individual rationality will fail. This means that the amount or quality of collective good provision to follow from individual rational behavior will fall short of what the aggregate of individuals in a group desire. In short, notwithstanding the fact that a group is nothing more than the collection of individuals who belong to it, individual rationality, even assuming it to be universal, will not secure the rational group outcome.

The Voluntary Provision Model and Olson's *Logic of Collective Action*

The initial reaction of economics to this understanding was to conclude that instead of individual action, society must rely on government power to enforce individual contribution via coercive taxation/expenditure. Olson's first insights came from taking the next step: because government itself is subject to the quandary that the free rider problem creates and, therefore, may not produce an optimum outcome, it cannot be assumed that government will necessarily or ordinarily close the gap between individual and group rationality. Olson, therefore, asked what to expect of individual voluntary behavior in the absence of governmental or coercive intervention. Such is the topic of *The Logic of Collective Action* (1965), Olson's Ph.D. thesis and first great contribution. Once the question was thus posed, it became clear that the range of circumstances where collective action obtained was far more vast, complex, and richer than the early oligopoly paradigm might lead one to expect. Moreover, contrary to simplistic theory, sometimes arrangements arise (in the form of intragroup monitoring or selective extra rewards to those who do not free ride) that allow the free rider failure to be reduced and possibly altogether circumvented. Olson's discovery and elaboration of the 'voluntary provision' model of public goods changed, in fact redefined, the topic for economists; it introduced public goods to other social sciences, especially political science and sociology and elevated it to a unifying principle throughout the social sciences. The result was an explosion of research into the structure of voluntary provision, and into the myriad of applications of the model, ranging from strictly economic to anthropological, legal, sociological, and political, from labor union behavior, to allocations within families, voluntary philanthropic giving for a group or social goal, and from public interest lobbying, special private interest favor seeking and professional associations to the behavior of nations as they formed alliances to combat common adversaries, or environmental challenges like ozone depletion.

In all of these instances, Olson discerned three factors paramount in explaining the degree of success a group has, absent government coercion, in providing itself with a collective good: these were (1) the size of the group, (2) the heterogeneity of its members, and (3) the ability of the group to offer selective incentives to individual members to induce contribution to the collective good. In fact, the international alliance example served as the first instance of voluntary provision that could be verified empirically. With coauthor Richard Zeckhauser (1966), Olson modeled the allocative behavior of the North Atlantic Treaty Organization (NATO) Alliance as it provided its constituent members deterrence against attack and defense should attack materialize. The Olson–Zeckhauser analysis comported empirically with the predictions from Olson's theory, namely, that when the membership of a group is heterogeneous, the large and/or rich members will voluntarily contribute disproportionately large shares of the total public good, an effect Olson had named 'exploitation of the great by the small.' Thus, crucially Olson–Zeckhauser demonstrated that Olson's insights into the applicability of economic structure to political phenomena could be formulated into rigorous logic and empirically tested against reality. Later extensions of the voluntary provision model have lead to surprising insights (Bergstrom et al., 1986) into equilibrium outcomes when individuals in a group interact but do not coordinate their interactions, including demonstrations that equilibrium group provision within a range is

independent of the distribution of a group's income or wealth among its members. This voluntary provision model and its Nash equilibria continue to be the paradigm for numerous behavioral patterns, from cooperation among countries in regulating the international economy to controlling pollution, to the economics of charitable giving.

Public Choice, Political Economy, and Olson's *Rise and Decline of Nations*

From the first principle of 'Public Choice' mentioned above, it follows that the extramarket behavior of the individuals who make up governments is itself governed by individual search for individual satisfaction. Always committed to individual rationality embodied in calculated decision, in the middle stages of his career, Olson's elaboration of the public choice theme develops several corollaries to this proposition.

First, rather than being a utopian instrument to correct social inefficiencies in the provision of public goods stemming from free rider behavior, government behavior itself is driven by free rider failures. The problem of correcting for free rider deficits is itself in other words beset by free rider effects; for example, who will voluntarily contribute the resources, attention, and energy necessary to form environmental policy to protect the public from degradation of the atmosphere? The answer is precisely not the general public, which benefits from environmental control but instead those interest groups sufficiently well organized to exact or induce participation by their membership. This leads to a second corollary.

The concept of collective goods and free riders applied to the larger social mosaic implies a hierarchy or cascade of nested interest groups. First of all, people will act in their own interests, not the interests of their group; but once or if they have successfully overcome intragroup free riding and harnessed their individual incentives to the group – if they ever do – then those groups will act in their own self interests, not in the interests of their larger society.

A third corollary applies these principles to redistribution, with introduction of the notion of a distributional coalition, a group that by collective or collusive action can gain an increased share of society's wealth not by working to create a larger societal total, but by imposing external costs on others in the society. Such groups of coordinated rent seekers work though various instruments, many effected and enforced by the government that they influence, instruments that include discriminatory taxes or tariffs, barriers to mobility, or to entry as well as downright corruption and theft.

It was Olson's focus on this structure that brought the free rider problem to the widest academic audience of sociologists, historians, and political scientists, and that showed the applicability of the idea to current world developments and practical policy. His formulation of the idea, propounded in *The Rise and Decline of Nations* (1982), assembles these corollaries into one grand principle: the notion that entire societies fail or succeed on the quality of their management of free riding. It is the success of interest groups in overcoming obstacles to their own collective action and the failure of any larger polity to overcome the obstacles to its collective need to leash protectionists that molds the destiny of nations. Moreover, there is an inherent tendency over time, Olson argued, for efficiency-destroying and innovation-strangling special interest groups to proliferate in stable societies, such as the United States and United Kingdom with institutions that survived World War II (WWII) more or less intact. By contrast, those societies that experience the social upheavals typical of war or revolution – like Japan or Germany at the end of WWII – find that special interest groups and distributional coalitions are dismantled, thereby giving the society as a whole another start at constructing social and economic institutions afresh, which will encompass the aggregate collective interest of all the people. The idea of social and institutional sclerosis sometimes called 'demosclerosis' was thus advanced as a crucial determinant of societal economic success. It was an audacious idea, but one has to be subject to empirical rejection. The idea was noticed by social scientists the world around and resonated in the popular press.

The Character of Governance: Olson's *Power and Prosperity*

The final focus of Olson's energy – summarizing papers from the last decade of his life in the posthumous *Power and Prosperity* (1999) – was on the greatest of the free rider puzzles of all: how does government even come into existence, given the immense obstacles to collective rationality presented by individually rational free riding? Reflecting on this question, he was well aware of the immense rewards a society reaps from establishing a peaceful social order, and submitting itself to the institutions of governance. So there is no doubt that good governance is in the collective interest of a society; by investing in certain public goods, governments can increase the productivity of the society dramatically, and this benefits everyone. Moreover, for groups larger than families or at most tribes, governments are the only institutions that can do this. These are public goods such as establishment of a rule of law, institution and maintenance of property rights, provision of common defense, stable currency, contract enforcement, elements of infrastructure, and public education and health, and so on. Such investments in public goods benefit everyone in the society by making its whole industrial, commercial, and economic base much more productive.

But, Olson was also deeply aware that provision of public goods is far from the only or even major function of government. A second function is redistribution. Historically, almost all systems of government have emerged as vehicles of redistribution from the people to an autocracy, monarchy, or oligarchy. Contemporaneously, our generation has seen massive increases in government-enforced redistributions throughout the world. These redistributions, which play so crucial a role in the political economy of the modern state, are undertaken by governments, which exact taxes from some groups and make transfers for the benefit of other groups. The beneficiaries in this process are in general the groups to whom governments are beholden, and the taxpayers those to whom they are not. Thus, (1) redistribution to favored interests and (2) allocation to enhance everyone's productivity are the two *de facto* primary economic functions of modern government. Public good, productivity-enhancing allocation, and group discriminatory redistribution are conflicting resource use

options between which any government must choose. Irrespective of its political makeup, this is a choice every government must make and a supremely important one for the welfare of its members.

But how is the conflict between the two objectives reconciled? In brief, Olson argues the redistribution that a society accepts is the price it must pay to achieve the gigantic collective benefits of peaceful governance. But a precondition for this bargain even to be struck in the first place is that free rider obstacles be overcome sufficiently for government to be enduring (Olson, 1991, 1993). Governance by transient 'roving bandits' is inefficient; only when the roving bandit settles down to become a 'stationary bandit' – that is, an established monarch or autocrat – can society enjoy the immense benefits of peaceful development. Assuming this much success in conquering free riding pitfalls, Olson then extrapolated a theme from earlier in his career: the idea of groups as differentiating themselves along a scale of their 'encompassing interests.' This is the notion that a group that reflects the interests of a large proportion of its society in its economic calculus will behave very differently from one with a narrow membership and support. The more encompassing group will internalize more of the cost it inflicts on the entire society in pursuit of its narrower self-serving distributional goals. This provides the clue to his discovery, with coauthor Martin McGuire (1996), that the political logic of these invest–redistribute decisions will rest on a spectrum between two polar extremes. At one extreme is an idealized, consensual democracy where all redistribution issues have been settled unanimously and taxation only serves public good investment objectives. At the other extreme is perfect autocracy ruled by a dictator who taxes and spends solely to satisfy his own selfish desires. This work then shows that realistic societies can be analyzed as a mixture, in fact a weighted average, of these two polar cases. Thus, in making the choice between investment in the entire society and redistributive taxation from the powerless to the powerful, every polity behaves somewhat like a pure democracy and somewhat like a selfish dictatorship. Informed by this logic, McGuire–Olson derive the allocation and distribution rules that various governments across the spectrum will follow, showing, for example, that even a purely selfish dictator (providing he controls an enduring government) will not only transfer resources to himself but also invest in his economy. Why? Because investment will make the economy prosper and add even further to the tax take. Also intriguing is the proof that all societies and forms of rule are limited by an automatic governor on their incentives to tax. This contradicts the pessimistic expectations of some political moralists that extension of the democratic franchise would necessarily induce endless voracious redistributive taxation, leading finally to the ultimate destruction of the economy itself. It demonstrates, to the contrary, that for every ruling group, incentives to tax reach a point well before confiscation where desired redistribution voluntarily ceases.

The thrust of Olson's thought toward the end of his life was to bring these insights to bear on the puzzling economic trajectory of the Soviet Union, which seemed so economically cumbersome succeeded by Russia whose fortunes so declined after its markets were unleashed.

Mancur Olson's Impact

Mancur Olson's legacy extends broadly across the overlapping frontiers of social science and philosophy. His life was marked by numerous conferences devoted to examination of his ideas and books devoted to his insights such as Sandler (1992). His impact derives first of all from his ability to develop a simple idea so that it becomes powerfully applied across a grand subject area. An enthusiast for basic ideas, and ever the economist, he illuminated political processes using economics ideas and showed how political processes could hobble economic productivity. The result was to gain far wider acceptance of economic method and theory in the work of political scientists. Many before Olson would take for granted that if some outcome should be beneficial to all members of a group, then the group would act in concert somehow to bring it about, thinking in terms of joint rather than individual action, without asking how the joint action would be enforced. It was no longer so after Olson. He had the rare ability to take highly abstract but ultimately simple ideas and to apply them to the reality of economic and political development. Because of his work, awareness of the difficulties and paradoxes of achieving collective rationality, no longer confined to a cadre of specialists, has entered into the discourse of the largest universe of social science and philosophy.

Concrete witness to his impact is the Institutional Reform and the Informal Sector project. This US Agency for International Development vehicle was created to promulgate Olson's ideas in more than 30 countries around the globe, many struggling with the reform and adjustment process in a transition from socialism. Although he explored and exposed the difficulties of achieving socially desirable outcomes through uncoordinated individual action, he was no naive advocate of central planning or coercion. For him, the operations of governments were to be subjected to the same analytic scrutiny as markets, and government failures had to be exposed just as fearlessly as market failures. Thus, it was within the practical context of practical reform of institutions that Mancur Olson's final contributions took effect as an advocate for the idea that good governance can manage free rider challenges and achieve prosperity in the developing world (Olson, 1996). His life was marked by innovative ideas, personal energy, and an unflinching conviction that institutional reform could yield prosperity over poverty. The now universal appreciation of the links between good governance and economic success is his living bequest.

Online Dating

Monica T Whitty, University of Leicester, Leicester, UK

Abstract

Ever since the early days of the Internet, men and women have been logging on to search for love. During this time there was much debate over whether 'real' relationships could be formed with 'strangers' online or whether instead these relationships were meaningless and potentially psychologically unhealthy. Theories such as the Social Presence and Social Context Cues Theory were developed to predict that online relationships were of little benefit to individuals. This article provides a summary of these early debates, and points out the importance of not drawing a distinction between 'physical world' versus 'virtual world,' but instead that there are many types of spaces online, with different features with different norms that govern these spaces. The article makes note of some of these spaces and draws distinctions between them. It also highlights the 'hyperpersonal' theory first noted by Walther (1996), which contends that under certain conditions individuals form closer relationships online than they would in the physical world. Contemporary examples of online dating examining online dating and social networking sites are examined to relook at early theories and point out how the different features and norms of the space lead to different trajectories when it comes to online dating. Finally, it examines a relatively new crime online, that exploits individuals hope to find 'true' love online – known as the romance scam. The theoretical reasons for its success are highlighted here.

From its early days the Internet has supported social interaction and the search for a soul mate. In early studies, there was much debate over whether 'real' relationships could be formed with 'strangers' online or whether instead these relationships were meaningless and potentially psychologically unhealthy.

As mentioned in the introduction to this article, in the early days of the Internet, there were two opposing theoretical views to online relationships: online relationships were shallow and meaningless versus the Internet provided new radical opportunities for forming relationships. When we consider these theories, we need to be mindful that the Internet was a very different space to how we know it today, and the types of people who inhabited the space were not represented of the general population. The virtual world was mostly constructed as text, where individuals' impression managed their online selves.

Social Presence Theory and Social Context Cues Theory

Advocates of Social Presence and Social Context Cues Theories took the view that online relationships had a noticeable deregulating effect on communication leading to unfulfilling relationships, that were low in intimacy (Hiltz et al., 1986; Kiesler et al., 1984; Sproull and Kiesler, 1986). Social presence was understood to mean the degree to which a person is perceived as 'real' and involved in mediated communication and scholars that devised these theories believed that given that online communication involved fewer nonverbal cues (such as facial expression, posture, dress, and so forth) and auditory cues in comparison to face-to-face communication, it was said to be extremely low in social presence and social context cues. According to these theorists, as social presence and social cues declines communication becomes more impersonal. In contrast, when more information is available about how one physically looks this leads to greater positive regard. Hence, given that there is less social presence online compared to other media online, communication was said to be less personal and intimate.

These views found some support by researchers. For example, Kraut et al. (1998) in a well-known study, referred to as the HomeNet Study, found that greater use of the Internet was associated with negative effects on an individual, such as decreases in the size of one's social circle and increases in depression and loneliness. In their longitudinal study, households who had never accessed the Internet were provided with a computer, a free telephone line, and free access to the Internet. During the course of the study, they tracked changes in psychological states over time. The study found a significant relationship between heavy Internet usage and loneliness. Kraut et al. argued that since initial loneliness failed to predict subsequent loneliness, the most likely explanation was that the increased use of the Internet was what caused the increase in loneliness. In other words, Internet usage was taking up time that could be better used for more psychologically beneficial interactions offline. Kraut et al. made the claim that *weak ties* were being established online, which were of poorer quality compared to the types of relationships, and strong ties already established offline.

Kraut et al.'s (1998) 'HomeNet Study' has been widely criticized. One of the major criticisms is that they used only three items from the UCLA loneliness scale to measure loneliness and their Cronbach's alpha of .54 was clearly poor (Grohol, 1998). Morahan-Martin (1999) points out that the sample size was too small and not randomly selected. Perhaps a more important criticism, however, is that Kraut et al.'s findings might only explain novice Internet users (LaRose et al., 2001). Moreover, as LaRose et al. (2001) have maintained, self-efficacy might be an important variable to consider. The individuals that spent more time online in Kraut et al.'s study might have been simply ineffective users of the Internet and the stress in trying to work out how to use this new technology might have caused them to become more depressed (Whitty and McLaughlin, 2007; Whitty and Carr, 2006). Interestingly, in the 3-year follow-up to the HomeNet Study the same

researchers found that almost all of the previously reported negative effects had dissipated (Kraut et al., 2002). Instead, higher levels of Internet use were positively correlated with measures of social involvement and psychological well-being. Perhaps such results might be explained by LaRose et al.'s (2001) claim that it is also important to consider self-efficacy. Whitty and Carr (2006) argue that participants in the HomeNet Study might have become more Internet savvy over time, which in turn altered the way they used the Internet.

Disinhibition Effect

Around the same time that theories such as Social Presence and Social Context Cues theories were being developed, other psychologists were observing a phenomenon fairly unique to online interactions, which they referred to as the 'disinhibition effect.' These individuals were observing that in some online spaces, are more likely to open up about aspects about themselves in cyberspace and act out behaviors they might not otherwise in traditional face-to-face settings (Joinson, 2001; Suler, 2004). Suler (2004) describes this as a double-edged sword as some people reveal secret emotions, fears, and wishes or show unusual acts of kindness and generosity, which he refers to as 'benign disinhibition.' Barak et al. (2008) found that because of the online disinhibition effect, individuals are able to open up more in online support groups. This, they argue, fosters personal empowerment, control, self-confidence, and improved feelings. In contrast, there are times when people are more rude, harsh critics, show anger, hatred, or even threats than they typically would be face to face. This Suler calls 'toxic disinhibition.' Cyber-bullying is an example of this type of toxic disinhibition. For example, when young people write cruel messages on social networking sites.

The disinhibition effect research demonstrated that there was a little more going on that those who subscribed to the social presence and social context cues theories. Although they too noticed that some online ties were 'weak' and found evidence for virulent relationships, at the same time they were finding the opposite results; that is, that individuals were self-disclosing more about themselves and being more kind than they would perhaps in the physical world.

Less Can Mean More

Others too were observing that traditional ideals and values important in the physical world were equally important online. Whitty and Gavin (2001), for instance, found in their study where they interviewed 60 Internet users, that ideals such as trust, honesty, and commitment were just as important in relationships formed in these spaces. Rather than finding evidence of less 'real' or less satisfying relationships online, some of the participants in their study reported that their relationships seemed to work better solely on the Internet. As this 18-year-old women reports:

> *It* [the relationship] developed through an interesting chat on IRC and a series of about 500 e-mails. The attraction was merely someone who cared and listened. He was very sensitive and caring, and his picture was hot! {laughs} … we exchanged addresses and he sent me presents on Valentines Day and Easter. We would write a two page e-mail every day, send sounds to each other, and eventually after 6 months we talked on the phone. Our phone conversation was very weak so we decided to stick to e-mail… We met after 8 months of exchanging e-mails. He was a great guy, and it would have worked but he lived in email. It was a good experience though and he was exactly like his photo.
>
> Whitty and Gavin, 2001, p. 628

In their study they also found that chat room users reported feeling less self-consciousness and less aware of being socially evaluated, which in turn allowed these individuals to reveal intimate details about themselves, while maintaining distance and personal space. Ironically, many of the male participants in this study believed that by disguising their identity they could be more emotionally honest and open.

Social Information Processing Theory

Given that researchers were finding that despite the lack of social presence and social context cues that 'real' relationships were forming online, theorists turned to explain the reason for these 'real' relationships. Of course, we need to be mindful that part of the explanation might be, as discussed earlier in this article, that individuals were getting better at communicating online and that different types of people were gravitating to the Internet. However, theorists noted that individuals might also be able to overcome some of the hurdles the Internet originally presented. Joe Walther is one such theorist who started to try to understand why 'real' relationships were emerging online.

While Walther (1995) subscribed to the reduced social cues view, he believed that many of these studies did not account adequately for time. Given the shortcomings of previous research, Walther and his colleagues sought to develop a more thorough understanding of the exchanges that take place in online environments. In doing so, Walther originally came up with the 'social information processing theory (SIP).' The SIP theory "refers to the way by which communicators process social identity and relational cues (i.e., social information) using different media" (Walther, 1995, p. 190). This theory proposes that the main difference between face-to-face communication and computer-mediated communication (CMC) is the pace that relationships develop in each space rather than capability to develop relationships. Walther argued that although CMC may be more aggressive at first, with time this dissipates. Walther (1992, 1995, 1996) stressed in his original thinking that many of the differences between online relationships and face-to-face relationships diminish over time, and although restricted bandwidth may limit the rate of information exchange, allowing longer and/or more frequent communication can alleviate this problem. However, Walther's theory did not end there – through extended empirical work, especially in lab environments, Walther started to notice that online relationships can be somewhat different to ones formed in the physical world. This led him to develop the theory of 'hyperpersonal communication.'

Hyperpersonal Communication

Walther extended his SIP theory to develop a hyperpersonal communication framework. This theory posits that "CMC users sometimes experience intimacy, affection, and interpersonal assessments of their partners that exceed those occurring in parallel FTF activities or alternative CMC contexts" (Walther et al., 2001, p. 109). Walther (1996) argued that people use the technical capacities of the Internet to assist in impression development. According to Walther (2007, p. 2539), the model "specifies several concurrent dynamics in sender, receiver, channel, and feedback systems that are affected by CMC attributes, which promote the development and potential exaggeration of impressions and relationships online …" According to this theory, receivers idealize partners because of the messages they receive, which they believe demonstrate the similarity in their online partner as well as a highly desirable character. In contrast, senders exploit the technology to selectively self-present aspects about themselves that the other would deem socially desirable. The CMC features allow one to be strategic in their presentation of self and the CMC environment creates a space where the outside world is filtered out and cognitive resources are instead employed to focus on the online communications. As Walther (2007) explains: "The CMC channel facilitates editing, discretion, and convenience, and the ability to tune out environmental distractions and re-allocate cognitive resources in order to further enhance one's message composition" (p. 2539). Once this cycle of communication has begun, Walther argues that "CMC may create dynamic feedback loops wherein the exaggerated expectancies are confirmed and reciprocated through mutual interaction via the bias-prone communication processes" (p. 2539).

Contemporary Theories about Online Relating

In modern times the Internet is becoming a more popular place for couples to meet. Dutton et al. (2008) sampled married couples in Australia, Britain, and Spain and found that 6% of married couples in the United Kingdom, 5% in Spain, and 9% in Australia had first met their partner online. The largest proportion of married couples that met online ranged from 26 to 55 years old.

As mentioned at the outset of this article, researchers need to be mindful that the Internet is not a homogenous space. More recent notions about the Internet examine the different spaces online, considering the different features of that space and the norms that govern that space. This article moves to focus on two such spaces to demonstrate by example, that one theory to one theory does not fit all: online dating and social networking sites.

Online Dating Sites

Online dating sites, in a fairly primitive form to the way we know them today, started appearing in the 1980s. In the early days, online dating was stigmatized and researchers were finding that shier people were gravitating to these sites to find a mate (Scharlott and Christ, 1995). In the 1980s these sites were largely text-based with limited space for individuals to create a dating profile in the hope to attract others. These days many online dating sites attempt to effectively match users of the service. Online daters are often expected to complete personality tests, as well as surveys on their interests and what aspects they are looking for in a partner. From there, matches are often given compatibility ratings. Other sites allow clients to find their own matches – where they need to work through a sea of profiles to make their choices.

Researchers have found that online daters often spend many hours contrasting an attractive profile (Whitty, 2008a,b,c; Whitty and Carr, 2006). Whitty (2007, 2008a) has argued that, as with newspaper ads, online daters are driven to 'commodify' themselves – ensuring they are presenting a self that others will feel compelled to 'buy' into. Some of the characteristics researchers have found that online daters consider important to present include: their looks, interests and activities, personality, humor, occupation, intelligence, uniqueness, and hopes and dreams (see Whitty and Carr, 2006; for an exhaustive list and percentages). Whitty (2007, 2008a) has found that online daters are savvy enough to know that simply presenting an attractive self on the site is not enough to attract the appropriate mate. Instead daters have to present a self that appears to have an honest and authentic presentation of themselves. Whitty (2007) has named this the BAR theory: that is, that to successfully attract a mate, online daters need to construct profiles that present a balance between an 'attractive' and a 'real' self.

Unlike what the hyperpersonal theory would predict, relationships developed between people that meet on dating sites are typically not intimate or close. This can be explained partly by the features of the space as well as the way relationships typically progress from these sites. As described above, online daters spend more time crafting a profile than they do getting to know one another. In fact, the processes involved in dating are quite different to the ones that Walther and others observed, where individuals spend much time communicating online, disclosing their private selves. Whitty (2008c) has drawn from Given's (1979) work on a traditional model of courtship to devise the five phases involved in online dating: *the attention phase* (which involves creating an online profile); *the recognition phase* (sending symbols such as 'winks' and 'kisses' to a profile that the person is interested getting to know the person whom it belongs to); *the interaction phase* (the daters begin communicating with each other through the site and then very quickly via Instant Messenger and e-mail); *face-to-face meeting* (this is a screening out process to determine if there is any chemistry and whether the person matches up to their profile); and finally *resolution* (starting to date). Given the way these relationships progress, there is not the opportunity, as the hyperpersonal theory predicts, for individuals to self-disclose in detail and become highly intimate and close with one another.

Social Networking Sites

Getting to know a person through a social networking site can again be potentially different to knowing someone via other online spaces or in our face-to-face interactions. Antheunis et al. (2010), for example, looked at the uncertainty

reduction process in initial online interactions on a Dutch social networking site. They found that participants used three types of uncertainty reduction strategies (URSs): passive, active, and interactive. Passive URS were the most commonly used, followed by interactive and active URS. Importantly they point out that:

> In contrast to text-based CMC environments, social network sites have more auditory and visual cues available and are relatively open systems. Apparently, this allows CMC participants not only to use interactive URS's (i.e., direct questioning and self-disclosure), but also to observe their target persons (passive strategy), or to ask other participants for information about the target persons (active strategy).
>
> p. 106

These researchers, however, also found that although the passive URS was the most frequently used strategy, the interactive URS was the only strategy that reduced the information seeker's level of uncertainty. As to be expected, they also found that a low level of uncertainty lead to social attraction. More importantly, however, they found that the relationship between level of uncertainty and social attraction is not direct, but rather moderated by perceived valence of the information (i.e., the extent to which an individual perceives the information of the target person as positive or negative, regardless of its credibility or quality).

Nosko et al. (2010) also ran a study to examine self-disclosure levels with Facebook users. They found that those seeking out a relationship on Facebook were more likely to disclose details about a number of topics, including views, relationship information, and personal information. In addition, they found that those seeking out relationships were more likely to disclose potentially stigmatizing information.

Social networking sites, such as Facebook, also play an important role once individuals have decided they want to date a person. Stern and Taylor (2007), for instance, found that individuals in romantic relationships used Facebook to check on the status of their relationship, commitment, and fidelity as well as to keep in touch with their partner.

Facebook provides a platform where individuals are able to monitor others, including loved ones. Researchers have found that this has lead to problems with individual's romantic relationships. Muise et al. (2009) found that increased Facebook use significantly predicted Facebook-related jealousy. Utz and Beukeboom (2011) examined SNS jealousy and SNS relationship happiness and the consequences of SNS use for romantic relationships. Overall, they found that participants experienced more happiness than jealousy in reaction to their partner's activities on social networking sites. However, individuals low in self-esteem were more SNS jealous than those high in self-esteem. Self-esteem also moderated the effects of SNS use and the need for popularity on SNS jealousy and SNS relationship happiness.

Dangers Involved in Online Dating

Although, as this article has demonstrated, the Internet provides new opportunities to meet romantic potentials and develop these relationships, researchers have found that criminals have found a new way to con individuals by setting up fake profiles and alluring victims into a fake relationship (Whitty, 2012; Whitty and Buchanan, 2012a,b). According to Whitty and Buchanan (2012a), the online dating romance scam emerged around 2007 and has its roots in paper-mail-based fraud. They have found that it is likely that at least 230 000 victims have fallen to this scam in Great Britain alone, and amounts lost range from £50 to £800 000. The online dating scam involves both identity fraud and mass marketing fraud. In this scam, criminals pretend to initiate a relationship through online dating or social networking sites with the intention to defraud their victims of large sums of money. Scammers create profiles with stolen photographs and at a very early stage the criminal declares their love for the victim and requests that the relationship move from the dating site to Instant Messenger and email, stating they want an exclusive relationship with the victim. Communication is frequent and intense, over periods of weeks, months, or even years. Phone calls might also be made. Fake documents are created to make the requests appear more genuine. Often small requests for money are made as a way of testing the waters and this is then followed by a crisis where the victims is asked for large sums of money that are urgently needed (crisis narratives include medical crisis, such as a car accident, business emergency, luggage needing to be released from customs containing gold bullion).

Relating this back to theories on online relationship development, Whitty and Buchanan (2012b) have argued that Walther's hyperpersonal theory can be applied to explain the success of this scam. Unlike typical relationships developed from an online dating site, where the individual physically meets the potential partner fairly quickly after meeting on the dating site, and spend little time getting to know them online; the victims of this scam spend copious amounts of time communicating with the criminal. Whitty and Buchanan (2012b) argue that the criminal uses Internet Communication Technologies (ICT) to groom the victim, sending poetry via email, and hours of time getting the victim to self-disclose highly intimate details about themselves and their lives via Instant Messenger. Victims often describe the relationship as the closest, most intimate relationship they have experienced in their life time, and admit that when they learn the relationship was fake, and even after losing large sums of money, they still want to maintain the relationship. This sometimes leads to a second wave of the scam, where the victim might have the criminal admit to deception, but during the scam they genuinely fell in love with the victim, and then the scam continues. The psychological impact from this scam is great, where the victim experiences a double hit of the loss of money and a close romantic relationship.

Conclusions

In the early days of the Internet a specific group of individuals gravitated to use it, in part to develop romantic relationships. In those days the Web was a space which mostly consisted of text, bandwidth was small, and download time very slow. Perhaps this accounts for the early theorists' views that the Internet is an impersonal space where it was believed that

relating online would lead to negative psychological well-being. The surprising result in the early days was that some online relationships were actually very intense and intimate and progressed healthy offline – a contrasting view that has been supported by empirical evidence. Despite these encouraging results, as the Internet has evolved we have learnt that we cannot develop one theory to explain all online relationships – individuals can be virulent and cold and calculating or intimate online, depending on the space and the norms of the space. Developing a relationship via an online dating site can be significantly different to meeting someone in a social networking site. The research on online dating has elucidated that there are certain skills involved in crafting a profile as well as making contact with others on the site. These relationships typically progress very quickly to offline settings, making it difficult to get to know one another online (a space where hyperpersonal theory is not supported). Facebook, however, is different again where individuals are often very strategic in the ways they impression-manage and the risks people are prepared to make to self-disclose. Facebook can lead to problems with already established romantic relationships, if individuals become too obsessive with monitoring their partner's activities. In addition to the new opportunities for online dating the Internet has opened up the floodgates for criminals to exploit spaces like online dating sites and social networking sites, to develop fake trusting relationships with unsuspecting victims and defraud them of large sums of money. The Internet will surely continue to grow and evolve over the forthcoming years, and no doubt will continue to play an important role in finding a romantic partner, and developing and maintaining a relationship with a loved one.

Online Pornography

Susanna Paasonen, University of Turku, Turku, Finland

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Public debates on the cultural role and status of pornography have intensified in the course of the 2000s. The abundant and ubiquitous accessibility of online pornography has impacted the overall cultural visibility of sexually explicit media materials, while the diversification of production practices and available content has pushed the established definitions and assumptions concerning the genre. This article explores the developments in online pornography, its cultural and social implications, the transformations that have occurred the genre, as well as the challenges that all this poses for scholarly investigation and public debate.

Public debates on the cultural role and status of pornography have intensified in the course of the 2000s. The abundant and ubiquitous accessibility of online pornography has impacted the overall cultural visibility of sexually explicit media materials, while the diversification of production practices and available content has pushed the established definitions and assumptions concerning the genre. In a parallel development, scholarly investigations on the topic have given rise to something to an interdisciplinary field that can be loosely categorized as 'porn studies.' This article explores the developments in online pornography, its cultural and social implications, the transformations that have occurred the genre, as well as the challenges that all this poses for scholarly investigation and public debate.

Abundance

The Development of Online Pornography

Pornography (or porn for short) was, in both its amateur and professional variations, a crucial element in the exchanges in bulletin board systems, Usenet newsgroups, Internet-Relay Chat, and file transfer through FTP that preceded the World Wide Web. Internet users have, for decades now, shared pictures, text, and video files harvested from their personal collections, copied from other sources, or produced by the users themselves. The easy usability of graphical Web interfaces since the launch of the browsers Mosaic in 1993, Netscape Navigator in 1994, and Microsoft Internet Explorer in 1995, in combination with the spread of network connectivity at the home and the workplace, marked both the gradual rise in popularity of the Internet as communication and storage medium and a dramatic change in the ways of distributing and consuming pornography through online platforms. The consumption of online pornography necessitates no visits to a specialty shop or orders through a postal mail catalog: online porn can be consumed for free, in the privacy of one's home or office, anonymously, and with a bewilderingly diverse sets of options.

Online porn was from the beginning both visual and textual, although image size and resolution were rather low due to the limitations of dial-up modem connection speeds. With the gradual increase in high-speed Internet connections, online porn grew increasingly audiovisual and high in resolution while web camera services established their popularity among the consumers of pornography. By the early 2000s, online platforms had challenged magazines and DVDs as the main distribution formats for pornography while also supporting interaction opportunities and peer production among users.

Throughout the 1990s, pornography was considered one of the few profitable forms of online content production – and, before online shopping and gaming picked up, perhaps even the only profitable one. The needs of the porn industry, which is understood here as a broad umbrella term for divergent production practices, aesthetics, and economies, drove the development of Web technologies and business practices from hosting services to safe credit card processing, banner advertisement, pop-ups, Web promotion, and streaming video technology (Bennett, 2001; Johnson, 2010). Although pornography is often excluded from overviews of Web history or presented as its 'dark side' (Parikka and Sampson, 2009), it has been an organic element of the evolution of the Web, both technologically and economically. New media theorist Wendy Chun (2006: pp. 78–79) points out that the success of online porn in the mid-1990s set the example for more mainstream companies on the possibilities of e-commerce, safe credit card transactions, and potential profits that could be made with the then emergent mass medium of the Web. In this sense, pornography functioned as a prototype for other kinds of online content production and product marketing.

Large porn companies with established production and distribution in print and video – such as the North American Playboy or Vivid – branched online only after the mid-1990s. Up until then, online porn enterprises were primarily independent and semiamateur. In the early years of the Web, before the development of specialized professions and skillsets such as those of a Web designer (Kotamraju, 1999), it was easy to code one's own site with only the basic knowledge of HTML. Small porn ventures could gain considerable visibility with relatively limited resources when the total number of global Web sites still remained modest (see Mash, 2004). Independent and alternative pornographies catering to subcultural markets and making use of community features grew in popularity during the late 1990s and their principles of operation influenced those of more mainstream companies seeking out new audiences and uses for their online platforms (Attwood, 2007; Paasonen, 2010). Enterprises smaller and larger targeted both

mass audiences and those adding up to highly specialized sexual niches. Consequently, the landscape of online porn was, and remains, both heterogeneous and fragmented.

Social Media

Since the dot.com crash of the early 2000s, Web site concepts and business models have been increasingly built on user-generated content, social media, and community platforms. In the late 1990s, 'content producer' was a paid profession similar to the editor of a print publication. Content producers wrote short articles and provided visuals for Web sites and portals in order to attract paying customers or at least returning users that would translate as advertisement value. In the 2000s, content production became the preoccupation of the users themselves whereas sites aim to generate profit by collecting user data and selling targeted advertising based on these data. Terms such as 'social media' or 'Web 2.0' that are used to describe and pigeonhole such developments may nevertheless be ahistorical in that they turn attention away from the abundance of user-generated content that largely characterized the Web cultures of the 1990s (Bruns, 2008: pp. 3–4).

With the introduction of tube sites – video hosting sites modeled after YouTube (launched in 2005) – porn consumption has been largely centralized to platforms such as YouPorn, Xtube, RedTube, Tube8, xHamster, and PornHub, many of which remain in the top 100 of globally most visited sites. On tube sites, users can browse for content in multiple categories, do searches, click on related content without leaving the site, and, if they so desire, tag and rate videos and comment on them as registered users. This marks a clear departure from the link sites and click-through characteristics of porn sites well into the 2000s. According to estimates, the overwhelming majority of online porn users – well over 90% – do not pay for the content they consume. The effect of tube sites especially on the consumption of freely available content is therefore considerable while less pronounced on the operating principles of pay sites.

These developments have marked a major increase in the accessibility, visibility, as well as popularity of amateur pornography. While amateur content was broadly circulated already on preweb applications and platforms and its histories well predate the era of online communication, its current visibility and accessibility is unprecedented. Together with both legal and illegal file sharing in peer-to-peer (P2P) networks, tube sites have contributed to the decrease in the profits of the more traditional (print and DVD-based) porn production. Since online pornography is largely consumed for free, it seems that the profits currently made in the field are shifting from production to distribution. On tube sites, private users upload content from heterogeneous sources whereas companies distribute short clips, teasers, and trailers of their work through the same platforms in order to attract paying customers to their own sites (Morris and Paasonen, 2013: pp. 555–556).

Random Estimates

The percentage of Web traffic taken up by online porn or the total number of porn sites are difficult to pinpoint due to highly variable estimates. Search engines routinely exclude pornography from their freely published listings of the most popular search terms. The so-called adult sites are similarly not necessarily listed among the top global sites. Openly available statistics, many of which are published by sites promoting filtering software, argue that porn comprises between 12 and 34% of all Web sites whereas peer reviewed studies have, for almost a decade, set the estimate to around 4% (e.g., Spink et al., 2006). The number of pornographic sites is certainly much smaller than the most cited and inflated statistics claim, yet it should be noted that an individual site can be massive and feature tens of thousands of videos and image files.

On the one hand, there is currently more online pornography than ever in open circulation: videos, still images, and texts, circulate from one platform to another, materials produced in analogue formats are digitized for online consumption, new content is uploaded on a daily basis, pornography takes up considerable bandwidth in Web traffic due to the use of video, and the absolute volume of pornographic content accumulates. On the other hand, the proportional volume of pornography in terms of all Web content is smaller than it was in the 1990s. The number of porn sites has steadily increased yet other forms of content have done so even more rapidly and steeply (Coopersmith, 2006). It is therefore not entirely fair to say that the Web is full of porn but neither is there any shortage thereof.

Diversification

Articulated Distinctions

Pornography has, at least since the 1970s, been strongly divided into different subgenres that are marked apart from one other, from couples' videos to BDSM (bondage, domination/discipline, sadism, masochism), or gonzo (reality-style pornography that makes use of point of view camera and where performers double as cameramen). Online pornography has nevertheless involved an unprecedented visibility of diverse sexual subcultures, preferences, and niches, partly in novel forms and combination (Halavais, 2005; Paasonen, 2011a). This is partly due to the diversification of porn production: professional, semiprofessional, amateur, and professional-amateur (Pro-Am, i.e., productions that make use of paid actors performing as amateurs) productions of different sizes and foci abound online. Online distribution is relatively inexpensive in that it does not necessitate the manufacture of physical products such as magazines or DVDs, and bandwidth and server expenses have gradually grown more affordable. Online distribution has afforded global markets for products targeted at relatively marginal audiences of the kind that would not be commercially viable on DVD (e.g., Lane, 2001: pp. 223–227; Bennett, 2001: p. 384). Companies and individual people upload porn for others to watch for free, for pay, and in exchange for a site membership registration. When applied to online pornography, the notion of the 'porn industry' is by necessity a rather elastic marker of individual and collective agents, some of which have no direct part in the production of porn and which merely facilitate its distribution and consumption, as though hosting services.

The diversification of the pornographic content is also partly fueled by the information architecture of the Web.

Images and videos are rendered searchable through indexing and metadata, namely descriptive textual information as for the style and contents of the imageries in question that is either embedded in the source code or provided as tags, captions, and descriptions on the site. Working in tandem, indexing, tagging, metadata, and search engines have rendered all kinds of distinctions far more pronounced than they have been in pornography distributed through other media platforms. Due to this development, differences between diverse subgenres, performers, body styles, acts, locations, and areas of production have grown increasing articulated and recognizable.

Addressing the fragmentation of the mass market of pornography, Mark Dery (2007) argues sites aim to grab potential users 'by their eyeballs' by showing them images that are surprising or even amazing in their novelty or eccentricity. In this sense, the attention economy of the Web – the need to mark one's site apart from the competition and to attract returning users – also fuels the diversification and fragmentation of the pornographic content. For some scholars, the accumulation of alternative, queer, and experimental pornographies online, together with the ubiquity of amateur porn that challenges the body norms and production practices of mainstream commercial porn, marks a rupture between traditional pornographies and the sexual exchanges seen as native to online platforms (e.g., Jacobs, 2007).

Camera Sites and the Boundaries of Pornography

The increased popularity of webcam sites offering live video connection and interaction possibilities that seem to optimize the promises of immediacy and presence associated with the Internet as a communication medium is a telling, and crucial, development on a number of levels. As mediated encounters, webcam sites blur the previously established boundaries of pornography and live sex entertainment such as strip shows. In connection to this, they blur the markers of professionals and amateurs connected to both sex work and the porn industry. Webcam workers may offer their services through sites that host hundreds, perhaps even thousands of models and that set strict conditions to the performers' actions. Alternatively, models may operate independently for a fee paid by the customers, or in return for gift cards and products purchased from their gift lists at online marketplaces. Webcam workers can be professionals such as porn stars, semiprofessional, amateur, or any combination thereof; they can sport a range of body styles, be of different ages, ethnicities, and nationalities, and their performances may be highly particular and involve multiple interaction possibilities.

Users may post their own images and videos, or those of their partners, on platforms ranging from tube sites to subscription-based portals, and openly accessible forums. Users may exhibit themselves on webcam sites such as Chatroulette, engage in explicit textual exchanges, write their own porn stories, perform sex with the aid of avatars in an online role-playing community, and post suggestive personal profiles on dating sites or social networking sites with the aim of finding partners for sex (Attwood, 2006: pp. 79–81). The definitions of the pornographic content easily grow elastic in the context of user-generated content and personal exchanges where – like ultimately in most human activity – sexuality plays a central role. The practice of sharing an image with another user one-on-one via e-mail or a private message differs from distributing the same image in a newsgroup, uploading it to Web-based image gallery, or making use of it as one's personal profile in an adult dating service. The crucial question then remains, how such user practices are channeled on and by different platforms, how and if these practices are incorporated in the creation of value for the platform in question, and what kinds of control users may have over the content they produce and upload.

Multiple Concerns

Bad Effects?

As both a media genre and a cultural trope, pornography is generally identified with the less positive social aspects, implications, and effects. In addition to being categorized low in the hierarchies of culture as filth and scum with no redeeming artistic or social value, pornography is seen as having negative effects on gender equality, violence against women, child development, as well as sexual identities on an individual level. Online access is regularly connected to porn addiction and studies have, for decades, aimed to point out the harmful effects of pornography on attitudes and behavior, especially those of heterosexual men toward women. Causal effects have nevertheless been hard to prove (see Malamuth et al., 2012; Hald et al., 2013). This problem is partly due to the fact that one set of cultural and social influences – such as particular pornographic images – are difficult to isolate and separate from others sources through and with which individuals make sense of the world and their place within it. Separating pornography from advertising, gaming, television entertainment, film, or social networking sites is alone difficult, not to mention attempts to separate media effects from the impact of one's family, educational background, hobbies, religious and political views, regional practices, or social networks.

Online pornography is paradoxically both ubiquitous and effaced: it is extensively debated, mundane and popular, yet something that is constantly edited and filtered out and that has been relatively disregarded as a topic of scholarly investigation until the very recent years (Paasonen, 2011b). Existing research remains patchy especially when it comes to production practices and patterns of personal consumption, given that most projects have focused on content analysis of pornographic content. The shortage of research on the topic is largely due to pornography being conceived of as a sensitive, difficult, and problematic object of study that is associated with multiple ethical and political concerns.

Children and Online Pornography

The volume and easy availability of online pornography have given rise to recurrent public concerns and occasional moral panics especially related to child pornography and children's access to materials deemed adult (e.g., Patterson, 2004: pp. 104–105). As early as in 1995, the *Times* 'cyberporn' issue liberally categorized over 80% of all photographs online as pornographic. Since only an estimated 16 million people used

the Internet globally at that point, the issue, with its inflated and unsubstantiated estimates, was effective in shaping the national imagination concerning the new medium and its contents in the United States (Chun, 2006: pp. 77–80). Due to prosecution, child pornography has nevertheless not been a visible feature on the Web and P2P networks for file sharing among users have been heavily regulated (Greenfield, 2004; Coopersmith, 2006: pp. 14–15). Child pornography is mainly distributed in closed networks and in the so-called deep web that is inaccessible to search engines and therefore excluded from mass consumption.

Child protection remains a central strand in debates on online pornography, often in connection with acts of regulation. In the summer of 2013, Prime Minister David Cameron's government in the United Kingdom announced that, in the name of child protection, all Internet service providers in the country are to block access to online porn unless the customer specifically sets the filters off. In Australia, online content is classified for similar ends. In countries where such centralized filtering is not in place, local regulation can be bypassed by hosting the illegal content on a server located in another country.

Antipornography Debates

Generally speaking, discussions on online pornography remain difficult to detach from the dualistic lines drawn along the axis of the antipornography and prosex (or anti-antipornography) advocacies, moral panics, and debates concerning censorship and freedom of speech that are characteristic to the discourse in the United States. Antipornography feminists have, since the 1970s, associated pornography with the sexual exploitation and objectification of women (see Boyle, 2010). Given that hardcore audiovisual pornography involves actual bodies having sex, antipornography feminists have defined it as documentation of sexual acts that should therefore not be protected under the freedom of speech (Mason-Grant, 2004).

Other antipornography advocates see porn as a form and symbol of decay on moral grounds: as immoral filth and scum that needs to be warded off from public consumption. Advocates for the freedom of speech have, for their part, argued for pornography as a form of fantasy, and prosex advocates have emphasized the importance of sexual self-expression and the subversive potentiality of pornography in defying bourgeois mores of good taste (e.g., Califia, 1994; Kipnis, 1996). The lines of debate tend to be polarized as being categorically for or against pornography. Both stances are equally generalizing in that they make use of pornography as an assumedly unified entity, cultural symbol, and symptom.

Pornification

A more general debate on the cultural role and social impact of pornography has recently been waged under the rubrics of the 'pornification' and 'sexualization' of culture, namely the ubiquity of pornography and sexually suggestive imagery in popular media (Attwood, 2006; Paasonen et al., 2007). In this framework, no clear distinction is drawn between hardcore and softcore pornography since the attempt is to examine the depictions of sexuality and sexual desirability across media culture, the ways in which they may have become transformed, and the cultural resonances that they may have. Such lack of conceptual specificity may, however, lead to analytical shortcomings, given that differences between the distinctly disparate aesthetics and politics that (hardcore and softcore) porn productions may hold easily disappear and the actual topic under discussion may become obscured. Diagnoses of 'pornification' may not, for example, afford sufficient distinctions to be drawn between softcore and hardcore pornographies, the public circulation of sexually suggestive imageries, and the explicitness of action shots. The demarcation line between porn and more mainstream culture remains one of acceptability and unacceptability. While popular culture broadly flirts with partial nudity, sexually suggestive poses and the aesthetics of softcore, similar mainstream appropriation does not extend to the fleshy aesthetics, control scenarios, and minute displays of bodily fluids featured in hardcore pornography. Explicit hardcore imagery is not circulated in advertising, music videos, or popular cinema.

The term pornification can also be seen to imply a process where pornography seeps into culture from the outside in whereas the process arguably works in reverse: pornography is an element of culture that is constantly being filtered off and barred from the culture properly by drawing lines between the obscene and the mainstream, the unacceptable and the acceptable. Diagnoses of pornification may then work to uphold the perspective that marks porn as other to culture, rather than framing porn as the product of a culture. Furthermore, these diagnoses may not allow for a sufficient contextual specificity in terms of different cultural and social contexts. Despite familiar, repeating emphases, debates on the cultural role of pornography and its mainstreaming in North America differ in obvious ways from those waged in Europe or Asia. When it comes to defining pornography and the dynamics of public debate related to it, North American perspectives gain much too easy predominance.

Critical Contextual Analysis

As discussed above throughout this article, the shapes and forms of available pornography have undergone drastic transformations in the course of digital production and distribution: the pornographic content has grown fragmented indeed. Digital and network technologies have opened up new forms of social circulation and exchange while also incorporating and appropriating familiar aesthetics, commodity forms, and practices of usage. Pornography can be soft or hard, airbrushed or gritty, and tender or aggressive, it is catered to users of different genders, preferences, interests, and nationalities, and it features female, male, and transgender performers alike. One key problem is that pornography is nevertheless constantly treated as an assumedly uniform category with a known, albeit much understudied, social meaning, and impact.

Studying one set of pornographic materials and their production says very little of others. Hardcore gonzo pornography of the 1990s, which profiled itself through scenarios of male domination and female submission, such as the videos of Max Hardcore, have been much critiqued for their misogyny, which has been their very key selling point. Expanding such critiques categorically to all gonzo, video productions, or

online pornography is nevertheless untenable, given that one set of productions aims to profile itself apart from the competition, and that pornographic subgenres and niches operate centrally through distinction: a queer-feminist porn production is clearly profiled apart from the 'girl-on-girl' scenarios targeted at heterosexual consumers (Ryberg, 2012) just as pornography of specific national origins can be marketed through its specificity and difference to productions from the neighboring countries. As already pointed out, the categories and tags on tube sites facilitate and encourage similar forms of distinction.

In terms of research methodology, analysis of text and image provides limited analytical possibilities for exploring or mapping out the context of production or the labor conditions, political underpinnings, ethical principles, and economic considerations involved. Amateur productions, for example, may easily be seen to connote pornography that is more ethical in its principles of production and more real, raw, and innovative in its aesthetics than commercially produced materials. Such categorizations largely ignore questions concerning power in intimate relationships and family practices: an image of domestic sexual intimacy or intensity may be uploaded for online circulation without the permission of the performer and acts may be performed under duress. Similarly, a theatrical, commercially produced scenario of dominance of submission with dramatic displays of physical discomfort may result from a completely voluntary arrangement with regulated work conditions, and with no duress involved. Categorizations or judgments concerning pornographic images or videos based on content analysis alone can tell of the aesthetics and representational politics practices at play but they should not be extended to speculations concerning production without any empirical evidence.

Conclusions

There is little doubt as to the social, cultural, and economical significance of pornography in contemporary Western culture. Pornographic imageries depict forms of sexual desiring and desirability, visceral lust, domination and submission, and they often do this through repetitive, formulaic, and stylized templates. The perennial appeal of pornography among consumers from diverse background alone speaks of its active role in shaping and contributing to cultures of sexuality. At the same time, this contribution is hard indeed to map or define in terms of precise 'impact.' The shortage of empirical ethnographic work on the consumption – as well as the production – of pornography across different national contexts sets serious limits to what scholars can claim to know about the genre and its social implications. Debates on pornography are far too often grounded in assumptions, rather than knowledge, of its meanings and effects.

The boundaries of the pornographic content have grown elastic with peer production, the flirtation with the aesthetics of pornography across popular media, and the diversification of production practices. All this necessitates reflexivity in terms of what is meant with the term 'pornography' and how it is used as point of reference. Rather than a cultural symbol or symptom, pornography needs to be seen as an umbrella term for practices, many of which are mutually contradictory and even incompatible with one another. Given the plethora of online pornography, it is impossible to identify one set of ethical, political, or aesthetic principles that would apply to all of it, or to pornography as the general marker of genre. It therefore remains crucial to resist generalization, to remain specific in one's analysis and insist on drawing distinctions between different sets of materials, which are critiques of contemporary online pornography to have analytical leverage or explanatory power.

Onomastics

Wilhelm FH Nicolaisen, University of Aberdeen, Aberdeen, UK

This article is reproduced from the previous edition, volume 16, pp. 10859–10863, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

'Onomastics' is the intellectual endeavor which studies names of all kinds, not simply as a subdiscipline of linguistics but involving several adjacent extralinguistic disciplines. In order to establish a sound basis for name studies, it is essential to clarify the distinction between names and words or, more generally, between lexicon and onomasticon. In the naming process, transfers occur not only from the former to the latter, but also from one name category to another. As name usage is the prerequisite for name survival, socio-onomastics has become a central concern of name studies. In a largely cross-disciplinary approach, literary onomastics, i.e., the study of names in literature, has recently become a strong focus, and an active and productive activity.

'Onomastics' (from Greek *ónoma*, 'name') is the intellectual endeavor which studies names of all kinds (geographical names, personal names, boat names, names in literature, etc.). As names are embedded in, and transmitted through, language their study is often regarded as a subdiscipline of linguistics, and more precisely of lexicology, the study of words. This limited approach, however, does not do them justice, for names are not simply words with additional properties, and therefore they transcend purely lexical considerations. In this broader sense, they are also the legitimate subject of investigation by scholars working in extralinguistic disciplines, such as history, geography, sociology, psychology, philosophy, law, religion, literary criticism, and so on. It is in this wider ambience that onomastics will be treated here. The most extensive and authoritative account of names and their study is to be found in *Name Studies: An International Handbook of Onomastics* (also containing articles in French and German), Eichler et al. (1995–96).

Names and Words

The study of names, whether pursued as an integral part of, parallel to, or complementary to the study of words, has a long and distinguished history, although its terminology and the concepts it represents have led to a certain amount of confusion, a state of affairs which has not been resolved adequately even in our time. It is therefore necessary to pay close attention to the criteria which are being applied in each approach. Furthermore, in English the situation is complicated by the fact that, in addition to its indigenous term *name* (Old English *nama*, *noma*), inherited ultimately from Indo-European and therefore shared with the other Indo-European languages, it has, among others, also adopted the term *noun*, which goes back to Latin *nomen*, via Old French *nun, num*, and is now usually applied to substantives. This contrast between *names* and *nouns* is, however, not carried through systematically, and one still comes across such largely synonymous pairs as *common noun* and *proper noun* on the one hand, and *common name* and *proper name*, on the other, in which *common* and *proper* reflect classical tradition. Though the term *name* and the concept behind it are consequently at least pan-Indo-European, it is advisable to treat its descendants with care within each individual language. Such caution is, naturally, also called for in connection with name studies in non-Indo-European languages. Otherwise, any attempt at a theory of names or, more correctly, a theory about names, is destined to founder from the outset. (For further reading see Algeo, 1973; Gardiner, 1954; Pulgram, 1954.)

Semantic Distinctions

Though names and words share many characteristics, they differ in one major respect which has fundamental consequences: their semantic properties. If words are to be used competently, they must have meaning on the lexical level; otherwise they fail to serve the purpose of linguistic communication. Such a condition is essential to words of all kinds, whether they apply to concrete (*table, stone, street)* or abstract (*kindness, politics, religion*) phenomena. Meaningless words cannot fulfill their connotative function which is inclusive in its potential reference to any kind of 'table' or any variety of 'kindness.' This basic prerequisite is not expected of names which function perfectly well without any lexical meaning in what has been called 'the speech act of identifying reference' (Searle, 1969, p. 174) which is both denotative and exclusive (*Aachen, Glasgow, Paris; Karin, Maggie, Robert*).

Although most names started out as words or combinations of words that, in their time, had been transparent semantically on the lexical level, it is their capacity to function while being opaque semantically that makes them such fascinating and useful evidence for scholarly investigation, i.e., for what has come to be known internationally as onomastics. What they do need instead of lexical meaning, however, is onymic contents – this city (*Toronto*), this hill (*Bennachie*), this person (*David Livingstone*), this ship (*Titanic*), this dog (*Rover*), etc. In this context, it is essential for effective communication that there is a minimum of shared knowledge about that content, in order to avoid misunderstanding or complete failure. We need to know names, not understand them. The investigation of brand names, which has become very popular in recent years, can be said to straddle onymic and extra-onymic fields of research (Eichler et al., 1995–96, Sect. XIX).

Name Clusters and Fields

Despite the basic role of names as identifiers of individual referents, to the exclusion of all others, the number of names which can justifiably be claimed to refer to just one place, person, boat, cat, etc. is very small in our day and age. For that reason, true individuation can only be expected in limited environments (one first name in one generation of a nuclear family, one street name in a small town, one fishing boat in one home port, one horse in one stable). It is, however, a truism that no name can function alone but can only be useful in relation to other names, either in loose name clusters or, particularly, in structured onomastic 'fields' (a metaphor borrowed from physics), such as all names in a family; all, or most, street names in a town; names of all fishing boats in a harbor (and perhaps even beyond); all names of horses in a stable. Research into 'onomastic fields' parallels the study of 'lexical fields' (Schmidt, 1973) but, because of their respective differences in semantic status, is subject to different criteria (Nicolaisen, 1998).

Lexicon and Onomasticon

It is customary to think of the inventory of words in any language as a lexicon of which dictionaries are the best-known repositories. The equivalent corpus of names may be regarded as an *onomasticon* which, like a lexicon, may range from all the names embedded in any culture or language to the personal inventory of names known to one individual. Their conventional home is the gazetteer. It is when lexical items cross the threshold from lexicon to onomasticon as part of the naming process that their semantic status changes drastically. Even if, as often happens at least in the initial stages, onymic items are still lexically transparent (*Neustadt, Westhill, Rose, Smith*), the recognition of that word meaning hardly ever interferes with the (newly) acquired onomastic contents, even if these two aspects apparently contradict each other, as in the case of a *Neustadt* ceasing to be a *neue Stadt* 'new city', or of a man named *Smith* becoming a baker. In fact, a *baker* called *Baker* is likely to be an amusing anomaly rather than the prevailing norm in cultures with heritable surnames. In this sense, the long-running controversy of whether a name is in essence more of a name when it is (lexically) meaningless than if it has preserved semantic transparency on the lexical level can be demonstrated to be based on false alternatives. This judgment is supported by the realization that not every name starts out as a word or word compound with lexical meaning, because any pronounceable sequence of sounds/letters can become a name, and in some instances there are intra-onomastic transfers in a personal name becoming a place name (*Jefferson*), a place name becoming a personal name (*Pittendriech*), or a place name or personal name becoming the name of a ship (*Deutschland, Queen Mary*). Sometimes this process can be repeated, as when the English place name *Washington* first turns into a surname and then into a place name again (*Washington*, DC *Washington* State).

Onomastic Methodology

It is clear that in such transfers from one onymic category to another, or in names with non-lexical origins, a search for the original word meaning would not only be fruitless but also inappropriate. Since they are, however, in the minority, and since much onomastic research has its origins in the investigation of linguistic history, it is not surprising that etymological approaches have been, and still are, very common, especially in the study of place names (*toponymy*). This is, in principle, not very different from the lexicographical search for the derivation of words insofar as its chief requirement is the utilization of the earliest recorded spellings or forms, but nevertheless differs from lexical etymology because its aim is to reduce the name to the word(s) it once was in the act of naming: nevertheless, etymological research must be regarded as a fundamental first step in most kinds of onomastic procedures, as long as its successful completion is not also taken to be their sole goal (*see* Etymology). The many volumes of the county survey by the English Place-Name Society, for example, speak of the necessity for, and efficacy of, this method (EPNS, 1924–).

Toponymic Research

The study of place names (Eichler et al., 1995–96, Sects. XV–XVII) has for a considerable time been one of the foremost occupations of the scholar of names. The main reason for this has been the very fact that names can function without the aid of lexical meaning, whereas words cannot. This characteristic has allowed names to survive not only when the words which have formed them have died out at an earlier stage of the language that coined them, but also to outlive the very death of that language itself and its replacement by another language. In Scotland, for instance, only a handful of words has been adopted by the English language from Gaelic, whereas the maps contain many thousands of place names of Gaelic origin; the same can be said of the Slavic ingredients in the vocabulary and toponymy, respectively, of the eastern parts of Germany. In some parts of Europe and in European-derived cultures, this process of toponymic survival at times of language replacement has sometimes been repeated more than once. In the north-east of Scotland, for instance, Pictish place names have survived from preGaelic times, and it is also possible to detect a preCeltic, i.e., preGaelic and prePictish layer of Indo-European river names ascribable to the same 'Old European' linguistic stratum which, on the European continent, is linked to the Bronze Age. Some of the major island names in the Northern and Western Isles reflect the sometime, presence of speakers of an as yet unidentified non-Indo-European language. In southern Europe, multiple layering in linguistic stratification is also demonstrated by toponymic evidence.

The value of place names as evidence for this kind of investigation increases with their relative antiquity. Research among living languages has shown that in periods of linguistic and cultural contact the main process by which place names pass sequentially from one language to another is chiefly by phonological adaptation. However, partial translation, full translation, and complete replacement also occur, albeit more rarely; it is also natural that many names do not survive language change. What has emerged from this type of study is the realization that lexical dialects and onomastic dialects are not always congruent (Nicolaisen, 1980). It has also become clear that the translations of maps showing the spatial

distribution of place names into maps demonstrating chronological sequences is fraught with difficulties.

Name Transfer

The kind of toponymic palimpsest which these processes create provides a key to a relative chronology in the settlement history of speakers of relevant languages. More often than not, individual strata, or the stratification as a whole, reflects the importation of languages from elsewhere. The settlement of the New World by Europeans since the sixteenth century is a particularly striking example, since many of the names designating new locations were imported unanalyzed from elsewhere, usually without regard to their semantic fitness (Zelinsky, 1967). It can also be shown that 'colonial' settlers take with them in their mental luggage not just a lexicon of words but also an onomasticon of name models which are applied to the new terrain in the creation of landscapes reminiscent of home (Nicolaisen, 1987). One instructive instance of this is the settlement of the Northern and Western Isles of Scotland from Norway, from the ninth century onward, for without names there are no landscapes and no habitats, but only wildernesses and disorientation.

Socio-Onomastics

Initially, name scholars concentrated largely on the naming process itself and on its product, the name, but in recent decades the focus of their research has shifted more to socio-onomastic concerns, and especially to the role of names in society (Eichler et al., 1995–96, Sect. XXI). Usage and process have therefore become more central to their discussions. There are various aspects to this new direction. A major facet of place names is, in this respect, their role in politics, especially in political change, of which the emergence of a 'new Africa' is an instructive example, having prompted the creation of a large number of country names in the post-colonial era (*French Soudan* becoming *Mali*, *Gold Coast* becoming *Ghana*, *Southern Rhodesia* becoming *Zimbabwe*). Of special interest is the Republic of South Africa, in which radical internal changes have necessitated the wholesale reconstruction of its place-nomenclature, a task in which scholars with extensive expertise in onomastics have become involved (Raper, 1998). More generally, in the 'global village,' the United Nations has created the 'United Nations Group of Experts on Geographical Names' (UNGEGN) to oversee particularly the standardization of names in official usage, a move which has, as a byproduct, created a greater awareness of exonyms (*Copenhagen* for *København*, *Cologne* for *Köln*, *Aix-la-Chapelle* for *Aachen*) and their legitimate but circumscribed usage.

A long-standing experience of professional involvement by name scholars in the shaping forces toward a politically, as well as linguistically acceptable toponymy is to be found in Québec and its aspirations regarding independence (Dorion, 1998); and the sociopolitical implications of the use of place names by speakers of minority languages in countries such as Italy, France, Switzerland, Belgium, the Netherlands, Spain, Scotland, etc. have attracted the attention of name scholars (Kühebacher, 1986), as have the alternative usage of place names in informal, unofficial onomastic registers and the minutiae of microtoponymic concerns.

Personal Names

It goes without saying that the study of personal names (*anthroponymy*) is central to socio-onomastic investigations, as names are an essential component of human beings as unique individuals, and of their role in society. Just as there are no landscapes without place names, there are no societies without personal names. Parallel to etymological investigations regarding other categories of names, a certain amount of basic research has gone into establishing the linguistic origins and meanings of personal names, but the main thrust has been toward a systematic investigation of personal names as markers of human identity, traditional family pressures, or fashionable models, in various contexts. These include the naming of children; the historical development of heritable surnames from their four main sources – patronymics, occupational names, nicknames, and place names – anthroponymic typologies; the morphology of personal names; the increasing use of middle names; the overt and covert use of bynames; continuity and change in favorite names, etc. (see Eichler et al., 1995–96, Sects. XI–XIII).

Names and Education

There has been a growing tendency to introduce the discussion of many aspects of personal names into the classroom, for didactic purposes (Franz and Greule, 1999). Their own names and other people's names are of interest to children from an early age, and psychologists as well as educationalists have studied their increasing awareness of names in the development of selfhood and in the process of socialization. Personal names also form an immediate basis for children's involvement in, and contribution to, such discussions, just as investigations into local place names provide convenient inroads into local history and spatial awareness.

Literary Onomastics

The study of names in literature (Eichler et al., 1995–96, pp. 533–536) attracted an increasing number of scholars in the last few decades of the twentieth century. Its double roots in onomastics and literary criticism have made it a truly interdisciplinary pursuit. Much of the research conducted in its early phases was directed toward the role of names in individual works by individual authors. This search for name inventories as texts within texts gave, and to a certain extent still does give, literary onomastics a strong bias toward intratextual questions. However, recently there has been a conscious movement toward intertextual approaches and names as devices in intertextual relationships, or as means by which the factual world can become fictionalized, and fictive persons and places can become factualized. A special branch of this approach is concerned with the translatability of names, on both the lexical and the onomastic levels, whereas other scholars are concerned with problems of name stylistics. The role of names as devices employed in autobiographical writings in attempts to create a credible past has also attracted special attention.

Conclusion

Having started out as a subdiscipline of linguistics and functioned for a long time as a pursuit which was, because of the special status of names, admirably suited to throw light on puzzling concerns of other intellectual endeavors, onomastics has gradually abandoned this handmaiden role and has developed into an independent, though amply connected, discipline which studies names as names, for their own sake, thus establishing a foundation for their effective investigations as interdisciplinary evidence. The introduction of socio-onomastic approaches has been especially productive in this respect, but onomastics has also widened its scope and diversified its methodology in other respects, in a concerted drive toward greater sophistication and a more systematic and systemic outlook. The growing scholarly interest in matters onomastic is reflected in the existence of several academic institutes devoted to name studies and usually attached to universities or academies (in Denmark, Norway, Sweden, Finland, Belgium, Scotland, England, Northern Ireland, etc.), as well as many international, national, and regional organizations in the field, and regular congresses and conferences, often dedicated to special facets of onomastics.

Editor's Note

The origins, history and processes of proper naming have continued to attract the attention of linguists, etymologists, sociologists, philosophers and others. Perhaps the leading journal in this field of inquiry is *Names: A Journal of Onomastics*, available online at: http://www.maneyonline.com/loi/nam. Readers may also be interested in *Onomastica Canadiana* (the official journal of the Canadian Society for the Study of Names): (http://www3.csj.ualberta.ca/sco/index.php/home/onomastica-canadiana/ Representative samples of current research in onomastics include Sofia Kotilainen, 2011; John Algeo, 2010; Lars Borin and Dimitrios Kokkinakis, 2010.

A great deal of onomastics research is essentially literary and studies the naming of people and places in the works, e.g., of Tolkein, Ursula LeGuin, Doris Lessing, or the Harry Potter novels (all subjects of frequently downloaded articles in *Names*), among many others. Another onomastics obsession, particularly among those of sociological persuasion, is trends in the naming of children. See, e.g., Jean M. Twenge et al., 2010; see also Stanley Lieberson, 2000.

Abstract

Learning and teaching in the open classroom is not a completed theory or system of education but, instead, a related set of ideas and methods. The four main operating principles that shape the open classroom (flexible use of space, multiple learning resources, students engaging in a variety of activities, teacher working with individual children or small groups) are explicated. The teacher's role as a facilitator of learning, which is not to judge but to reflect back to the student the consequences of the student's behavior by guiding the student through questions about activities and discoveries relative to the learning experience, is detailed. The effectiveness of the teacher in the diagnosis of learning events, which is to understand the student's thinking process by listening to and questioning the student so that the student can follow their own thinking, is presented. Five learning techniques commonly utilized in the open classroom are identified. An eight-dimensional taxonomy of the teacher's role, which is widely accepted, is introduced. The current negative status of the open classroom is noted.

Introduction

The open classroom is a highly structured and deliberately organized learning environment in which the teacher performs a significant and crucial role. This kind of schooling is known by several of its manifestations: open school, integrated day, open corridor, informal education, and British infant schooling, terms used to describe a learning approach, which discards the traditional classroom setting in favor of a less formal, highly individualized atmosphere in which direct experiences are central to the learning process. The adjective 'open' recurs because this form of education is not circumscribed in classroom space, time blocks, age grouping, or even standardized curriculums. Instead, each child proceeds at his or her own pace and according to his or her own interests within a rich and carefully patterned climate in which active investigation and enjoyment of varied materials lead to the learning of skills and concepts in an integrated, rather than an isolated, manner. This departure from traditional teaching methods affects the role of the teacher as it does the behavior of the students.

Although an agglomeration of concepts from a variety of sources have contributed to open-education theory, including Rousseau and Froebel, the theoretical basis of the open classroom is found in the work of Piaget who was frequently identified in the Plowden Report as being central to an understanding of the process of learning in the open classroom. This document recognized and authenticated the informal styles of teaching and learning that were developed in English primary schools during the previous four decades and investigated by Gardner at the University of London (Horwitz, 1979).

As a result of the impact of the Plowden Report upon American teacher advocates, 50% of all schools built in the United States during the late 1960s were of open design and a similar percentage of open schools were built in Canada, New Zealand, Australia, and the United Kingdom (Bennett et al., 1980). In addition, open classrooms have appeared in Japan, Israel, Thailand, and Norway (Bennett, 1981).

Learning in the Open Classroom

The Learning Environment

The underlying assumption of open classrooms is that in an enriched and carefully planned environment that supports the natural drive toward learning, children learn in encounters with the materials and people around them at their own irregular and individual pace. Children learn most intensely when they are interested and understand the relevance of what they are doing. The open classroom represents a way of thinking, a way of living with children in a learning environment that meets the individual needs of the students, and therefore its curriculum is individualized.

Four operating principles govern the learning environment. First, an open flexible space divided into functional areas rather than one fixed homogeneous unit. Second, the environment is rich in learning resources including concrete materials, books, and other media. Third, the students are engaged in a variety of activities and levels of operation utilizing the contract-commitment method in which each student 'contracts' to do a certain amount of work, or to complete a project within a specified time limit. In this dynamic atmosphere, where learning cuts across subject lines, students are free to talk to each other, move about the room, and they have a significant degree of responsibility for their own progress. Fourth, the teacher divides the time into small, concentrated periods, working with individual children or small groups, rather than addressing the whole class as one group all day.

Open-classroom teachers are firm in their assertion that the teacher's primary responsibility is to create an environment that stimulates learning and is altered and expanded as the needs of each child change and his or her interests become more complex. The child's response to the environment becomes the starting point for learning because children learn from the things they do and understanding comes through personal experiences. In this environment, the teacher develops a uniquely close relationship with each child, as learning is dependent upon the sensitive responding of the teacher to the needs and interests of the individual student. This

cultivated skill demands that the teacher become immersed in each child's activity, identifies the moment of readiness, and gently guides the child toward direct exploration and experimentation.

Learning Events

In the diagnosis of learning events, the role of the teacher is to understand the child's thinking process. By listening and questioning, the teacher draws the child out so that the child can be assisted in realizing their feelings, plans, and details. Teacher interviews illustrate the delicacy used to determine when to intervene, to push, or even to assist. "She stretches her empathy for potential, she thinks with the child as he discusses. The 'tuning in', the thinking 'with', the seeing with a 'child's eye' are part of the response to a child's own question. It is this question which a child must follow to follow the development of his thinking, that is prime to the teacher – not her own preconceived questions and answers" (Weber, 1971, p. 229). The teacher's intention as facilitator is not to judge but to reflect back to the child the consequences of the child's behavior by guiding the child through questions about activities and discoveries relative to the learning experience (Barth, 1972). Because diagnosis occurs constantly during teacher–child interactions, errors are acceptable as they provide necessary feedback for continued, guided learning.

Through frequent note-taking describing the child's feelings, attitudes, and experiences, the teacher assesses and evaluates growth and learning. From this perspective, formal evaluation procedures are ineffective because, rather than being preoccupied with standardized and normative expectations, the teacher is vitally concerned with knowing that each child is making the best possible use of his or her environment and that he or she is making progress. Careful observation of experiences, linked with accurate recording, constitutes the scientific study of the learning process.

This effectiveness in the diagnosis of learning events depends entirely on the teacher's knowledge of the child's ability, individual needs, stage of development, and learning style. The teacher's focus is on the child who, in turn, is expected to accept both responsibility and internal personal control. Barth (1972) extends this idea by identifying the child as 'an agent of his own learning' and teachers as 'facilitators of learning' who encourage, help, and assist rather than prescribe, mold, coerce, or manipulate. As a facilitator of learning, which is a highly individual process in which teaching styles are as numerous, complex, and individually effective as learning styles, there is no one specific approach to teaching. In addition, in the multiaged open classroom, students of proven ability, together with parent volunteers and aides, assist other students who are having difficulty in assimilating the knowledge, as research has shown that children benefit from differentiated staffing in which contacts with more than one teacher is more beneficial than having the same teacher all day long. Peer tutoring, where students must think through a topic carefully because they are responsible for teaching it to other students, and collaborative learning, where students share responsibility for learning something and must organize themselves and the topic to do it well, are necessary learning activities in the open classroom.

The belief that children can sit passively and absorb information is not one of the assumptions on which learning occurs in the open classroom but, instead, children must be actively engaged in the process of their own learning. Perkins (1995), in investigating the practice of ability grouping and tracking in K-12 education, viewed the open classroom (with heterogeneously mixed grades) as a superior learning environment because research shows that students understand and retain what they study when instruction engages them in thinking about, and with the content of, their curriculum. Perkins' thesis is that learning is a consequence of thinking, and if students are not constructively engaged and connected with their thinking processes and their curricular studies, they will neither fully understand nor retain them. From his perspective, the teachers' basic job in an open classroom is to ensure that the students do a majority of thinking about and with the content of what they are learning. This perspective implies a number of learning techniques: *problem-based learning* (where students study content by seeking out the information needed to solve the problems); *project-based learning* (where students engage in complex and often socially meaningful projects that enable them to gain content knowledge); *engagement in understanding performances* (that ask students to use what they know in order to demonstrate and build their understanding); *infusion of critical and creative thinking into subject-matter instruction* (where students learn to analyze, critique, defend, adopt alternative points of view, and ask 'what if' questions); and the use of *authentic problems* (that have real-world significance and a messy open-ended character). Although thinking-centered learning can be complex and challenging for teachers and administrators to sustain, the ways to configure thinking-centered learning are endless.

A Learning Concern

There does, however, appear to be a danger that students in the open classroom may display less involvement in their activities and, consequently, learn less. Large discrepancies in time on task appear to be widespread as the findings reported by Bennett (1981) on open education in Britain are very similar to those reported by Fisher et al. (1978) in the United States. "It is of interest to note that the curriculum areas which are allocated the most time show the poorest involvement levels" (Bennett, 1981, p. 23). In addition, transition time (from one activity to another), which was studied as part of a survey in the United Kingdom (Bennett et al., 1980), observed examples of wasting time and concluded that students in open schools spend too much time in transition from one activity to the next or from one space to another. Similarly, New Zealand elementary students who were taught at tables rather than seated in rows had increased peer interaction and transition time between activities.

Teaching in the Open Classroom

Important Teacher Functions

As teachers in the United Kingdom have frequently pointed out, the teacher's primary responsibility is to set the mood or climate of the learning environment as the needs of each

student change. In this stage-setting role, the teacher functions as a stimulator who encourages and guides but does not direct children. The teacher sets up opportunities for learning experiences and children's questions become curriculum-starting points. In fact, the teacher's role is to not impose on children, but to closely cooperate with their native interests and drives so that whatever they are led to do is viewed as something that comes out of themselves. Weber (1971), who calls this 'opening up a child's purposes,' values respect for the child's questions and purposes as serious forces in learning, while other educational theorists maintain that demonstrating respect for children and managing the learning environment are key teacher functions. Doyle (1986) characterized the open-classroom teacher as an effective manager who ensures that students are concentrating on appropriate work in an environment where they have a high degree of choice.

Common to all open-classroom facilitators is an enormous trust in learners and the ability to relinquish large amounts of control. Facilitators are more effective if they themselves are involved in learning and challenge their own beliefs and practices when confronted by students. Because, generally speaking, there is no standard curriculum imposed upon the student, three teacher functions have been identified as critical roles of the open-classroom teacher: individualizer of instruction, resource person and counselor, and provider of suitable materials and activities.

Walberg and Thomas (1972) identified a wide range of beliefs and behaviors about the teacher's role, which were grouped into eight themes that are multidimensional and interactive in nature, yet discrete enough to serve as an organizer for an understanding of the teacher's role in the open classroom. This eight-dimensional taxonomy, around which clusters of significant research have been conducted, includes *instruction* (guidance and extensions of learning), *provisioning* (provisioning the classroom for learning), *diagnosis* (diagnosis of learning events), *evaluation* (reflective evaluation of diagnostic information), *humanness* (respect, openness, and warmth), *seeking* (seeking opportunities to promote growth), *self-perception* (the teacher's view of herself and her role), and *assumptions* (ideas about children and the process of learning).

Planning, Relationships, and Management Skills

Research into open-classroom processes reveals that effective teaching requires a high degree of planning, positive personal relationships, and excellent classroom management skills. The teacher creates the environment by restructuring the dimensions of time, space, materials, grouping, and communication. The classroom reflects a diversity of homemade materials to interest the students, books geared to a wide range of reading and interest levels, and a variety of carefully planned activity areas that encourage the student to explore.

Personal relationships are positive as the teacher interacts easily with students who enjoy being around him or her. The teacher is a 'real' person, cognizant of and able to express feelings, needs, attitudes, and motives. Consequently, effective open-classroom teachers exhibit characteristics of self-acceptance, self-respect, security, and self-confidence; they are encouraged to be themselves and to reject adopting the role of a teacher at the expense of being oneself.

Several important aspects of teacher classroom management, which are more vital in open than in traditional classrooms, focus on clarity of explanations, vigilance and mobility, and pupil independence. Clarity of explanations is crucial in open-classroom teaching as students ought to have a clear idea of what the project entails and the procedure for accomplishing the task. Vigilance and mobility indicates that the effective open teacher has excellent eye contact, and is able to split attention between the individual or group the teacher is working with and the rest of the class. Periodically, the teacher scans the class and is mobile enough to intervene in any problem before it escalates. This vigilance is transmitted to the class when, at intervals, the teacher publicly reviews the progress of different students or groups of students. Another message regularly transmitted is that of pupil independence so that the teacher is not overwhelmed with six or eight students gathered around the teacher's desk or trailing the teacher around the room.

Teacher Characteristics, Attitudes, and Reactions

The redefinition of the teacher's role as that of a facilitator, which encourages short-term decisions directed toward individual students, increases cooperation and communication among faculty and staff members. This research conclusion was reinforced by Harrison and Glaubman (1990) when they studied a systematic random sample of 42 Israeli elementary schools of which 17 had been implementing open-education practices for at least 3 years. Teachers in the open-education schools were significantly younger, had less experience than teachers in traditional schools, and reported having more frequent discussions of school goals and school problems with administrators, supervisors, parents, and members of the community. They used more resources for curriculum development and, as might be expected, the Israeli teachers in open schools described their school decision-making process as being more decentralized than teachers in traditional schools. Finally, Israeli teachers, who taught in schools that adopted the open-classroom approach, reported significantly more skill development, as measured by the number of hours of school-base training, than did teachers in traditional schools.

Schubert and Baxter (1982) documented a close relationship between teachers' attitudes toward open education and noncognitive student outcomes. Teachers have almost uniformly rated themselves as more open than they are and the difference is especially pronounced in the traditional classroom. When open and traditional classrooms are compared, students in an open-space school or a closed-space school (where teachers have favorable attitudes toward open-education principles) consistently scored higher with regard to level of curiosity and self-esteem than students of teachers with unfavorable attitudes toward open education. A significant sample of public school teachers, who taught in both open and traditionally constructed schools, had significantly more positive attitudes toward open education than teachers who taught only in open-space schools. Consequently, there is a positive relationship between the number of years of teaching experience and attitudes toward open education because teachers who taught 10 years or more in the open classroom were significantly more positive in their attitudes toward open education than teachers who taught less than 10 years.

Because intrinsic rewards (i.e., to play a significant role in students' lives) are important for open teachers and because the classroom is the major arena for the receipt of the rewards (Sederberg and Clark, 1990), teachers in open schools, generally speaking, show no significant inclination to move back into the self-contained classroom. However, 10 Canadian studies detailing adverse teacher comments report increased workload and insufficient preparation time, as teaching in an open classroom requires continuous innovation, monitoring of students' performance, and well-developed skills in maintaining order without being authoritarian (Traub et al., 1976). New Zealand teachers stated that increased workload was their major problem and that demands on them were very high, citing the necessity for continuous student evaluation and careful curriculum planning. This teacher reaction to the open classroom was reinforced by Australian teachers who maintained that the open-classroom workload was having a negative effect on their private lives (Angus et al., 1975).

Conclusion

Research that indicated that cognitive achievement levels in open classrooms were not significantly different from those in traditional classrooms initiated the decline of open education in the United States and by the late 1970s the movement was in retreat. Today, the literature is clearly characterized by its critics but, because widespread research has indicated that students in open classrooms are more independent, less conforming, act more cooperatively, are more attentive and participate more actively in class discussions, and display more creativity than students in traditional classrooms (Rothenberg, 1989), open-classroom learning strategies continue to be implemented in Western Europe, North and South America, and Asia as many schools continue to offer students the option of learning in open classrooms.

Openness to Experience

Abstract

Openness to experience is best understood as a multifaceted personality trait that covers a wide range of behavioral inclinations, attitudes, and interests associated with seeking for novelty and variety. Openness and its narrow traits (e.g., intellect, culture) are meaningfully linked to intelligence, academic achievement, creativity, social/political attitudes, religiosity/spirituality, subjective and psychological well-being, and work outcomes, which are discussed in detail.

Background, Definition, and Measurement

Openness to experience (in short, openness) is most commonly recognized as one of the Big Five personality dimensions and is associated with adjectives such as 'intelligent,' 'original,' 'curious,' 'broad-minded,' 'artistically sensitive,' and 'introspective.' Until recently, empirical research involving openness has been rather fragmented, mainly due to discord regarding its exact conceptualization and measurement. The divergence in definitions is perhaps best reflected in the often imbalanced contents of frequently used personality inventories that emphasize either the intellectual *or* nonintellectual aspects of openness, but rarely both. Recent personality literature addressed this imbalance by adopting a dual label for this construct, 'openness/intellect.' Most notably, DeYoung et al. (2007) factor analyzed the Abridged Big Five Circumplex measure from the International Personality Item Pool (AB5C-IPIP) and the Revised NEO Personality Inventory (NEO-PI-R), and identified two aspects (i.e., traits at the intermediate level of specificity), which were labeled as openness and intellect. However, in order to avoid any confusion around the fact that 'openness' can be used as both an aspect of openness to experience and as a shorter name for the general openness to experience construct, this article refers to these two aspects of openness to experience as *culture* and *intellect*, respectively.

Recently, Woo et al. (2014a) introduced a three-level structural model of openness to experience (http://www1.psych.purdue.edu/~sewoo/openness.php). This model was derived from a factor analysis of 36 existing measures of openness-related scales, which yielded six facets: *intellectual efficiency* (i.e., processing novel stimuli quickly, remembering information, being knowledgeable and intellectual), *ingenuity* (i.e., mental agility in manipulating ideas or concepts, refining existing information, creating something entirely new), *curiosity* (i.e., being inquisitive, perceptive, desiring to learn about scientific principals and related topics), *aesthetics* (i.e., appreciating various forms of art, open to aesthetic experiences), *tolerance* (i.e., enjoying learning about different cultures, attending cultural events, befriending people from other cultures, immersing oneself in a foreign culture when traveling), and *depth* (i.e., desiring to gain insight into self/world and to self-improve, discussing philosophy, self-reflecting, meditating).

According to Woo et al.'s (2014a) model, openness is a broad, multifaceted construct that embodies how one typically deals with novel stimuli. The narrower traits of openness encapsulate more specific behavioral patterns adopted by individuals that describe *how* people seek out, process, and manipulate novel stimuli. Novel stimuli can appear in either an 'encoded' form (e.g., symbols and equations used in scientific theories and models) or a 'raw,' preprocessed (e.g., shapes, colors, tastes, and people) form. Accordingly, Woo et al. categorized the six openness facets into two aspects, 'openness to intellectual stimulation' of encoded stimuli (or *intellect*, in short) and 'openness to cultural experience' or raw stimuli (or *culture*, in short). In further support of this, they presented a confirmatory factor analysis result that a model with the six facets and the two aspects of openness fit the data best. Woo et al. (2014a) also introduced a measure specifically designed to capture their theoretical model, which has been validated across three distinct samples from the United States and China.

Other Models of Lower-Level Openness Structure

In their renowned lexical study, Saucier and Ostendorf (1999) factor analyzed adjectives judged to be associated with openness, and identified three facets: imagination, intellect, and perceptiveness. The imagination facet had the highest loading on the openness factor and was marked by adjectives such as creative, inventive, clever, and innovative. The types of adjectives that loaded on their intellect facet described an individual who was intelligent, analytical, and knowledgeable. Lastly, the perceptiveness facet, which had the lowest loading on openness, was marked by adjectives such as perceptive, insightful, and foresighted. Based on the content of their facets, Saucier and Ostendorf's analysis provided a facet-level structure associated almost exclusively with intellectual functioning (e.g., inventive, analytical, insightful). While extremely illuminating, this methodology was unable to capture the vitally important experiential facets of openness that we now know compose the culture aspect of the construct.

Questionnaire-based studies, on the other hand, tend to reveal a much broader configuration of the openness construct. Costa and McCrae's (1992) NEO-PI-R is a good example. Its openness measure consists of six subscales (or facets): fantasy, aesthetics, feelings, actions, ideas, and values, which are based on their theoretical perspective of highly open people as being "imaginative, sensitive to art and beauty, emotionally

differentiated, behaviorally flexible, intellectually curious, and liberal in values" (McCrae and Sutin, 2009: p. 258). One of the strengths of this taxonomy is that it more accurately captures the domain of the multifaceted nature of openness, however, this taxonomy is limited because it was developed primarily based on the authors' intuitions rather than on a thorough, empirical and theoretical basis. As noted by Costa et al. (1991), they identified six facets for each dimension of the Big Five "not because each is naturally divisible into six parts, but because at least six distinctions were suggested by the literature, and more than six scales would tax the user's ability to learn and remember the facets," (p. 888).

On the other hand, openness facets of the Abridged Big Five Circumplex scales from the International Personality item Pool (AB5C-IPIP; Goldberg, 1999) had a clear theoretical rationale in their derivation. Each facet of the AB5C-IPIP was intended to represent a combination of two 'pure,' lexically derived Big Five factors (Hofstee et al., 1992). The assumption was that, by exhausting every possible 2-factor combination of the Big Five factors one would produce the most comprehensive range of Big Five facet-level traits. As a result of this pairing, the AB5C-IPIP contains nine openness subscales: intellect, ingenuity, reflection, competence, quickness, introspection, creativity, imagination, and depth (readers interested in the actual items of these scales may refer to http://ipip.ori.org/newAB5CKey.htm). Although a compelling methodology, we note that the AB5C approach was largely based on the notion that the core of 'Factor V,' a neutral label for openness within the lexical tradition, is 'creative mentality' (Johnson, 1994: p. 311). This inevitably biased these nine facets toward the construct's intellectual side, while essentially ignoring the cultural and artistic side of openness, as well as the vast range of stimuli associated with it.

Hough and Ones (2001) took yet another approach by consulting subject-matter experts to develop the openness of taxonomy. By aggregating opinions of experts, they proposed six openness 'working taxons' (complexity, culture/artistic, creativity/innovation, change/variety, curiosity/breadth, and intellect) and further listed some of the existing scales they believed to be associated with each taxon. The advantage of this approach is that it likely reflected a diverse range of researchers' experiences, and therefore a more balanced view of openness. The limitation of this approach may be that it is difficult to check for redundancies or to estimate the degree of relations between each proposed facet in a quantifiable, systematic manner.

Lastly, using a critical incidents sorting methodology, followed by theoretical discussions among subject-matter experts and subsequent meta-analytic investigation, Connelly et al. (2014a) identified four 'true' facets of openness: aestheticism, openness to sensation, nontraditionalism, and introspection. In addition, they also found four compound traits that were thought to be a result of both openness and other Big Five personality factors: thrill-seeking and variety-seeking were identified as reflective of high levels of openness and extraversion, and low conscientiousness; openness to emotions and innovation were identified as reflective of high levels of openness, extraversion, and emotional stability. Their final list of openness facets did not include certain constructs that represent curiosity and/or typical intellectual engagement, which was attributed to the fact that the subject-matter experts who participated in the theoretical sorting process did not see that they could be distinguished from the global openness trait. The authors noted, however, that including such constructs within the construct of openness is crucial, and as such, measures specifically designed to capture such facets are necessary.

Relationships with Other Constructs

Intelligence

It is widely recognized that individuals high in openness tend to seek intellectual stimulation and activities, behaviors which encourage further development of intelligence. Consistent with this, many empirical studies have found robust, positive correlations between measures of openness and cognitive abilities. Moving beyond the relationship between broad level openness and intelligence and taking into account their lower-level structures allows for a more nuanced understanding of how these two constructs are related. Past research that considered lower-level openness traits has suggested that the intellect aspect is primarily responsible for the relationship between openness and intelligence (e.g., DeYoung et al., 2014). This notion is directly supported by a recent discovery that measures of intellect were significantly associated with measures of *g*, verbal and nonverbal ability, whereas measures of culture (which DeYoung refers to as 'openness') were only associated with verbal ability measures (DeYoung et al., 2014).

Academic Achievement

In addition to general intelligence, openness has also been repeatedly linked to other various indicators of success in academic settings. Research shows that openness is positively related to factors such as deeper approaches to learning, intrinsic motivation to succeed in college, investigative and artistic interests, college GPA, primary school grades, SAT verbal section scores, as well as higher levels of educational attainment. However, recent research has suggested that the magnitude of correlation between openness (as a broad trait) and academic performance is often fairly modest, at best.

Further, researchers are not in agreement about the underlying psychological mechanisms by which openness influences academic success. One possible argument is that the positive predictive relationship between openness and academic success can simply be attributed to the conceptual overlap between the intellect aspect and intelligence. In line with this, Heaven and Ciarrochi (2012) found that openness to experience predicted increased academic achievement, but only for those who were high in intelligence. Some even argue that the intellect aspect of openness simply reflects intelligence, and that intelligence should be considered a part of personality (e.g., DeYoung, 2014).

Creativity (*see* Personality and Creativity)

Openness has shown consistent overlap with creativity-related constructs. Woo et al.'s (2014a) facet-level taxonomy of openness includes ingenuity as one of the openness facets, which was linked to high scores on Goldberg et al.'s (2006)

IPIP Creativity scale and other measures of creative personality. In line with this finding, previous empirical research has established a positive relationship between openness and creativity (e.g., Dollinger et al., 2004; Feist, 1998; Kaufman et al., 2009; McCrae, 1987; Nusbaum and Silvia, 2011). These studies considered creativity in contexts such as organizations, workgroups, academia, art, and science, as well as in various forms such as creative accomplishments, creative behaviors and/or performance, creative/divergent thinking, and self-ratings of creativity.

The culture and intellect aspects appear to have differential relationships with creativity-related constructs. For example, DeYoung (2013) posited that culture (which he called 'openness') would be more strongly associated with artistic creativity and intellect would be more strongly associated with scientific creativity. Similarly, Nusbaum and Silvia's (2011) study found that culture predicted creativity but intellect did not, when the assessment was geared toward artistic creativity. These findings echo previous research showing that the aesthetics facet of openness (a facet within the culture aspect) had the strongest relationship with artistic creativity whereas the ideas and values facets (facets within the intellect aspect) had the strongest relationships with scientific creativity (Perrine and Brodersen, 2005).

Political and Social Attitudes

Openness is the only Big Five personality factor that has consistently and uniquely predicted political orientation, with higher scores significantly associated with a stronger endorsement of liberalism. Liberals' "preference for social change and equality reflects and reinforces motivational needs for openness, creativity, novelty, and rebelliousness" (Carney et al., 2008: p. 817). Open individuals also tend to express less support for a government restricting civil liberties of prisoners and violating their human rights (Swami et al., 2012).

Beyond linking openness with specific social and political orientation, Mondak and Halperin (2008) found that people with high levels of openness also tend to possess more political interest and knowledge, engage in political conversations more actively, be more outspoken about their political beliefs, and have high levels of internal political efficacy (i.e., perceived understanding of government systems).

Religiosity and Spirituality

McCrae (1999) once noted that openness seems to be the most relevant personality trait to the topic of religion. In general, openness and its facets appear to be differentially associated with religiosity and spirituality.

With respect to the linkage to religiosity, some studies have found that liberal and fundamentalist Protestants were significantly different from each other on their level of openness (i.e., liberals higher on openness than fundamentalists; Streyffeler and McNally, 1998), and that individuals with high openness are less likely to endorse religious fundamentalism in general (Williamson et al., 2010). Also, Dollinger et al. (1996) found that those high in openness were less likely to value *salvation* and more likely to value *self-direction*. However, this research is somewhat mixed with a few studies not finding significant correlations between measures of openness and religious orientations (e.g., Robbins et al., 2010), while other studies have found significant relationships (e.g., Streyffeler and McNally, 1998), suggesting that more systematic research is needed.

While the exact relationship between openness and religiosity is mixed, research suggests that openness does tend to be positively correlated with spirituality. Duriez et al. (2004) found that openness was related to a tendency to deal with religion in a symbolic (as opposed to a literal) way, but was largely unrelated to a tendency to accept the existence of a transcendent reality (which is characteristic of the modern definition of spirituality). Further, based on a sample of 256 students studying education in a southern area of Spain, Saroglou and Munoz-Garcia (2008) found that openness facets were differentially related to religiosity and spirituality. While spirituality and religiosity were negatively correlated with openness to actions, spirituality was positively correlated with the values, feelings, aesthetics, and fantasy facets, whereas religiosity was negatively correlated with the ideas facet. A recent meta-analysis by Saroglou (2010) adds much needed clarity to this topic: he found that while openness was unrelated to subjective religiosity it was positively related to spirituality and faith maturity, and negatively to religious fundamentalism.

Subjective (and Psychological) Well-being

There seems to be lack of consensus on how openness relates to subjective well-being. Some researchers have argued that openness to experience is a 'double-edged sword' that predisposes individuals to feel both negative and positive emotions more intensely and to experience more positive and negative emotional states (McCrae and Costa, 1991; Gonzalez-Gutierrez et al., 2005). However, a meta-analysis by DeNeve and Cooper (1998) did not find strong support for this idea; it was revealed that openness was (positively) correlated with positive affect but not significantly related to negative affect. After a decade, during which numerous studies were published in the realm of positive psychology, Steel et al. (2008) sought to update and extend the findings from DeNeve and Cooper's (1998) meta-analysis. Steel et al. (2008) showed that openness generally had a smaller correlation with subjective well-being than the other Big Five personality factors, but was positively correlated with happiness (mean $r = 0.13$), positive affect (mean $r = 0.20$), and quality of life (mean $r = 0.16$), while being largely uncorrelated with negative affect.

Another line of psychological research of well-being proposed the construct of psychological well-being. Compared to subjective well-being, psychological well-being draws more heavily upon existential issues around basic life challenges and human development (Ryff, 1985). Schmutte and Ryff's (1997) study of midlife adults found that openness significantly predicted self-reported personal growth (defined as "a sense of continued growth and development as an individual" (p. 551)), which is conceptualized as one of the major domains of human functioning, thus contributing to one's psychological well-being. Further, Keyes et al. (2002) found that those with higher levels of *psychological* well-being than *subjective* well-being tended to have higher levels of openness. Based on these findings, Keyes et al. (2002) suggested that highly open individuals'

emphasis on personal growth may come with a cost regarding negative feelings and evaluations of life.

Work Outcomes

As described earlier, openness is positively associated with cognitive abilities, creativity and innovation, curiosity/willingness to learn, and adaptability to change; it seems intuitive that openness should predict individuals' effectiveness in the workplace. Surprisingly, however, relatively little evidence has been accumulated for the validity of openness in predicting job performance in general (e.g., Barrick and Mount, 1991).

Some have attributed the lack of evidence for openness' predictive validity to conceptual and measurement issues in previous research (see the Section Background, Definition, and Measurement for a detailed discussion of this issue). Given the multifaceted nature of openness, researchers proposed that a more detailed, nuanced investigation of the openness construct and its narrow traits may yield a better understanding of its relationship with job performance (Paunonen and Ashton, 2001; Woo et al., 2014b).

Woo et al. (2014b) suggest that as the measurement specificity of openness increases (i.e., from general, aspect, to facet), stronger correlations tend to exist between the components of intellect and the outcome variables. For example, at the facet level of the intellect aspect, the ingenuity facet had the strongest association with task performance, the intellectual efficiency facet predicted turnover, and the ingenuity facet predicted leadership effectiveness and adaptive performance. However, no such relationships were found for other facets, or at the broader levels of the openness construct, demonstrating the importance of the lower-level structure of the intellect aspect.

Others have proposed that openness may only predict certain types of performance/work outcomes, and that such prediction may be further moderated by situational factors (e.g., Tett and Burnett, 2003). In line with this, studies have found that open individuals perform better in jobs that encourage new behaviors and ideas (Bing and Lounsbury, 2000), as well as in jobs which value innovation and creativity (Pace and Brannick, 2010). Additionally, people higher in openness adjust more rapidly to cross-cultural settings (Lievens et al., 2003; Shaffer et al., 2006) and jobs that have changing and diverse work environments (LePine et al., 2000). Thus, supporting the possibility that a thorough understanding of the effects of openness may require an understanding of the situational factors that are present within an individual's work environment.

On the other hand, high levels of openness may not always be a good thing. For example, some research has suggested that highly open individuals may be more prone to quitting their job than others. Zimmerman's (2008) meta-analysis showed that openness was positively related to voluntary turnover, even after controlling for prior intention to quit. Similarly, Woo's (2011) study on 'hobo syndrome' suggested that those with high levels of openness are more likely to have an attitudinal and behavioral tendency to quit (and change) jobs more frequently compared to others (i.e., display frequent quitting behavior accompanied with positive attitudes toward quitting). All in all, these findings suggest that openness likely has complex relationships with workplace outcomes.

Abstract

For millennia, opium was celebrated for its beneficial medical effects with no mention of the dangers of addiction. In the eighteenth century, the first documented cases of opium addiction appear along with prohibitions and illegal opium markets. This happens in China, and, then, in the early twentieth century roughly similar events take place in the United States. The transition from use to abuse is accompanied by changes in self-administration techniques (e.g., smoking), drug potency, economic conditions (e.g., an increase in disposable wealth and leisure time), and individual differences (e.g., genetic-based metabolic factors).

Archaeological evidence reveals that humans have been using mind-altering substances for thousands of years, and botanical and anthropological studies suggest that human drug use may be much older, perhaps stretching back to the Paleolithic Age. The inhabitants of early Neolithic settlements left behind fossilized psychoactive plant materials, wine-stained pottery, and containers that once held cannabis and ephedra (e.g., McGovern et al., 2004; Merlin, 2003). However, fossils and pottery may not capture the true age of psychotropic drugs. The opium poppy is a cultigen that has not-known wild variants; this suggests an association with humans that predates the development of pottery. In support of the botanical evidence, anthropologists (e.g., La Barre, 1970) report that hunting societies placed more importance on drug-induced experiences than did agriculturists, suggesting that mind-altering substances were known prior to the advent of agriculture. Thus, our hominid ancestors may have been using intoxicants well before the Neolithic period. In contrast, the historical record provides no consistent evidence of drug abuse until relatively recent times. Descriptions of what we now call 'alcoholism' did not appear until the early seventeenth century (e.g., Warner, 1994), and accounts of opiate addiction first appeared in China in the eighteenth century (Spence, 1975). Thus, any mention of drug abuse comes quite late in the history of mind-altering substances. Indeed, commentary prior to the seventeenth century routinely praised opiates for their restorative powers, and early discussions of the ill effects of alcohol focused on drunkenness, with no mention of alcoholism. Other drugs have similar histories. For example, cocaine and marijuana were also once perceived as largely beneficial agents that promoted well-being. However, the story of the transition from use to abuse is best told by opiates. Opiates have long been the prototypical addictive drug, and we know much more about the history of opiates than the histories of cocaine and cannabis.

The Opium Poppy

The opium poppy is a widely cultivated annual herb that thrives in many temperate and subtropical regions of the world. Its scientific name, *Papaver somniferum*, translates as 'sleep-inducing poppy.' Although best known as a source for narcotic drugs, the plant also has nonintoxicating uses. Its seeds are tasty and can be turned into oils that are used in cooking, lighting, and painting. Its flowers are prized by gardeners and florists, ranging from white to pale blue to fire-engine red. Even its stalks serve practical ends. Some dairy farmers claim that poppy-fed cows produce the best milk for making yogurt (Booth, 1996). But, the opium poppy is most famous as the source of morphine. Morphine is nature's most potent pain killer, antiquity's most celebrated palliative, and the basis for heroin, the most notorious of all addictive drugs.

Opium

Opium is derived from the sap of the poppy's seed pod. This is a globular structure that begins to ripen once the poppy's petals have dropped off. Starting at about the size of a pea, it reaches the size of a small egg in about 10 or so days. As it ripens, the pod fills with morphine-rich sap, which can then be extracted by hand or machine. The non-mechanized method, which was universal until recently, requires only a sharp knife. The farmer scores the bulbous pod so that the sap oozes out and coagulates on the plant's surface. The sap is then scraped off, dried, and shaped into an 'opium cake.' The cake contains about 10% morphine by weight, plus a number of other psychoactive alkaloids, of which codeine is the best known.

Opium History: From the Neolithic to the Seventeenth Century

Sixth millennium BC European communities provide the earliest unambiguous evidence that the opium poppy was harvested for human use. Litter from these early settlements includes fossilized domesticated grains, the skeletons of domesticated animals, and fossilized opium poppy seeds and poppy seed cakes. Poppy seeds also show up in a structure, dating from 5700 BC, which archaeologists speculate was used for religious rites (Merlin, 2003). However, given the poppy plant's various uses, it is not possible to say definitively that Neolithic Europeans took advantage of the plant's mind-altering properties.

Representational artifacts provide the first direct evidence that opium was valued for its subjective effects. Mid-fourth

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45023-3

millennium Sumerians inscribed clay tablets with an ideogram that refers to the opium poppy and has been translated as 'joy plant.' The Ebers papyrus, dating from approximately 1550 BC, lists some 700 medicinal potions, including one for colicky babies. It instructs concerned parents to mix opium with fly droppings and administer for four days (Booth, 1996). Bronze Age Greek artifacts (1600–1200 BC) depict the opium seed capsule in association with the gods of the night, sleep, dreams, and medicine (Nyx, Hypnos, Morpheus, and Asclepius, respectively). Greek myths and Homer's epics tell of opium's narcotic properties. Theseus uses opium to put Cerberus to sleep, the many-headed dog that guards Hades. In the Iliad, which is believed to date from the eighth century BC, Helen mixes 'nepenthe' with wine to soothe the distraught survivors of the Trojan War. Scholars believe that nepenthe was a mixture that contained opium.

The early written accounts of opiates were universally positive. In classical Greek and Roman texts and tales, opium soothes pain, quiets coughs, calms fractious babies, and relieves grieving warriors of their painful memories. There is no mention of abuse or even recreational use. The positive slant could of course be a matter of selective reporting. However, classical Greek and Roman essayists and philosophers valued moderation and did not hesitate to chastise their follow citizens for drunkenness and gluttony. (In *The Republic*, Plato describes drunkenness as a selfish myopic state and likens it to the psychology of lunatics and tyrants.) Thus, it is reasonable to suppose that if even a small number of people routinely abused opium, the philosophers and orators who stressed a balanced life would have held them up for criticism.

In the following centuries, medical texts become more detailed and comprehensive, thereby opening the way for negative as well as positive comment. But in regards to opium, the narrative turns even more salutary. Paracelsus (1493–1541), the leading medical figure of the sixteenth century, refers to tinctures of opium and alcohol by the made-up word 'laudanum,' a neologism derived from *laberle*, the Latin verb for 'to praise.' Elsewhere he refers to opium as the 'stone of immortality,' suggesting that opium extends life. Several generations later, Thomas Sydenham (1624–89), who is sometimes referred to as the father of English medicine, is even more laudatory. He writes, "among the remedies which it has pleased Almighty God to give to man to relieve his sufferings, none is so universal and so efficacious as opium."

Opium Becomes a Drug of Abuse

Opium's reputation is soon to change. In the first quarter of the eighteenth century, negative comments regarding opium and opium users begin to appear. In 1729 a government prohibits opium for the first time. These events take place in China.

Opium Smoking in China

In the early seventeenth century, shops in Jakarta and South China seaports began selling mixtures of opium and smoking tobacco. Soon after, Chinese living in Taiwan and along the Fujian coast began smoking pipes filled just with opium. This was new. For the first time in recorded history, significant numbers of people were using opium for nonmedical purposes (Zheng, 2005; Spence, 1975). Also for the first time, opium became the focus of criticism. The diary entry of a soldier stationed in Taiwan in 1724 notes that opium smoking was:

> … a harmful trap, set by the barbarians in Taiwan to ensnare Han Chinese: neophytes were given free meals and free opium at first, but once they were hooked they were made to pay. Addiction was common in Taiwan, and smoking had been widespread … . (Spence, 1975, pp. 147–148)

At about the same time, a local government official adds that opium smokers 'were either the criminal or the gullible.'

These passages are remarkable. For more than 5000 years, the historical record contains nothing but acclaim for the benefits of opium – "a gift from God that extended life" – but with the advent of smoking and recreational use, it turns into a quagmire for deviants and fools.

Opium Addiction in China

The disparaging remarks were followed by the first nationwide prohibition on opium. In 1729, Yongzheng, the emperor of China, banned opium smoking. However, the ban did not stop the growth of opium smoking. Opium smoking became widespread, affecting all social strata. Historians claim that the increase was directional, starting first with the educated and wealthy (e.g., Spence, 1975; Trocki, 2002; Zheng, 2005), but Chinese government officials of the day described opium's dissemination the other way around – with the 'poor and disreputable infecting' the upper classes, particularly their children. However, there is no doubt that over the course of the eighteenth and nineteenth centuries, opium smoking in China dramatically increased. Foreign interests, particularly the British East Indian Company, exploited the demand for opium. They joined forces with local warlords to set up illegal opium markets. This led to a series of wars with Britain over the importation of opium. Britain easily vanquished the Chinese forces. The resulting peace agreements called for the emperor to accept the opium trade, cede Hong Kong and other territories to the British, and submit to political and economic concessions that together initiated 'China's century of humiliation.'

On the basis of Dutch and British trading company records, historians have estimated the size of the opium market and the prevalence and frequency of opium smoking in China over the nineteenth and early twentieth centuries. Between 1729 and 1906, tons of imported opium increased from approximately 15 000 to 26 000. Domestic production increased dramatically as well so that at the beginning of the twentieth century, the Chinese were consuming about 54 000 tons of opium a year. In many towns, opium shops greatly outnumbered tea and wine shops, and in some regions, opium was the most widely cultivated plant (e.g., Fields and Tararin, 1970; Newman, 1995; Spence, 1975; Trocki, 2002). On the basis of these figures and other historical documents, Newman estimates that in 1906 between 50% and 60% of the population smoked opium two to four times a year, about 12% smoked once or twice

a day, and about 2% smoked four or more times a day. These numbers suggest that the percentage of Chinese who would have met today's criteria for addiction in 1906 was somewhere between 2% and 12%. Other experts come up with similar estimates of overall opiate use (e.g., Spence, 1975; Trocki, 2002). To help put these numbers into perspective, there is wide agreement that the prevalence of lifetime opiate addiction in the United States has remained well below 1% for years (e.g., Anthony and Helzer, 1991; Stinson et al., 2005), whereas lifetime alcoholism rates have been steady at about 13% for some time (e.g., Hasin et al., 2007). That is, in the late nineteenth century, the prevalence of opiate addiction in China may have been equal to the prevalence of alcoholism in the United States in the early twenty-first century.

In 1799, Emperor Kia King issued a more far-reaching ban on opiates, which was accompanied by a frequently quoted rationale for the new prohibitions. A version in Latimer and Goldberg's (1981) history of opium reads:

> The use of opium originally prevailed only among vagrants and disreputable persons … but has since extended itself among the members and descendants of respectable families, students, and officers of the government. When this habit becomes established by frequent repetition, it gains an entire ascendance, and the consumer of opium is not only unable to forbear from its daily use, but on passing the accustomed hour, cannot refrain from tears or command himself in any degree. The extraordinary expense of this article is likewise to be noticed … which the fortunes of the bulk of the community are unable to satisfy, and are therefore wholly dilapidated and wasted away. (p. 106)

The emperor's account, although now over 200 years old, describes many of the key elements of addiction as it is understood by researchers and clinicians today. Frequent use leads to withdrawal symptoms, compulsive use, and a general loss of will. To make matters worse, the opium market was an economic drain on China. The middlemen traded away valuable goods (e.g., silver and porcelain) to foreign traders – which they could then sell for a profit – for a commodity that literally went up in smoke.

Why China?

For thousands of years, opium was the physician and herbalist's most revered and powerful potion. But as soon as large numbers of people began using opium recreationally, it became a vector for personal and social problems. The most obvious explanation for this turn of events is the change in the mode of self-administration. Inhalation bypasses first-pass drug metabolism, allowing the circulatory system to deliver morphine molecules to the brain in a matter of seconds. As a result a given amount of morphine is much more concentrated when it reaches the brain, thereby producing a much stronger effect. The stronger effect attracted many new users.

But smoking cannot be the sole reason that opium addiction first emerged in China. By the eighteenth century, tobacco smoking was familiar to much of the world and opium was available throughout Europe, North Africa, the Near East, and Asia. The British were the major opium dealers and were ever eager to create new markets for their vast Indian opium fields. Opium smoking could have taken hold virtually anywhere. Yet only in China did it take place on a scale that prompted government prohibitions. Similarly, merchants from many countries encountered opium smoking in Southeast Asia in the seventeenth century, yet only those from China found an eager market for this new practice when they returned home.

Many factors contribute to drug abuse, and accordingly there are a number of different accounts of why opiate abuse first emerged in China. Spence (1975) suggests that opium smoking offered relief from the boredom and frustration that was endemic to the rigid social structure of eighteenth and nineteenth century China. Zheng (2005) makes the case that Chinese cultural traditions paved the way for opium smoking. Wealthy households and businessmen offered their guests and clients an after-dinner smoke of opium along with fine teas and tobacco. Moreover, in China opium already had a link with pleasure. According to some texts it was an aphrodisiac – a belief that seems to be unique to China. Thus, an aesthetic sensibility that extolled private pleasures prepared the way for opium smoking. Trocki (2002) emphasizes economics, particularly China's advanced consumer culture. He contends that China had a highly developed market system (relative to Europe), and that Chinese consumers embraced opium as the next, new, 'had-to-have' luxury.

Opium and the Genetics of Alcohol Metabolism

These three theories are reasonable and not mutually exclusive. It is easy to imagine that individuals trapped in a rigid social structure would turn to opium, and, similarly, it is easy to imagine that a culture that emphasized sensual pleasures, particularly those that could be pursued in quiet repose, would welcome opium, and given how avidly Chinese took to tobacco smoking, it is easy to imagine that they were now looking for something new to spend money on. However, these traits are not unique to China. People everywhere seek sensual pleasures, wish they could advance to a higher social status faster, and like new things. Since opium addiction occurs first in China, there should be one or more etiological factors that are unique to China.

The genetics of alcohol metabolism differentiates China from most other countries. The key fact involves the second step in the metabolic chain. First, alcohol dehydrogenase transforms alcohol into acetaldehyde, which is toxic. Then acetaldehyde enzymes detoxify the acetaldehyde. However, some people inherit an allele that results in a slow-functioning acetaldehyde enzyme. When they drink, the acetaldehyde toxins increase, resulting in dizziness, flushing, and increases in heart rate. These effects are correlated with low rates of binge drinking and low rates of alcoholism (Luczak et al., 2001). The allele that codes for the less functional acetaldehyde enzyme is much more common in Asians than in Europeans. For instance, in a study conducted at the University of California at San Diego about 50% of the Chinese students were positive for the slow-metabolizing allele, whereas for students of European ancestry there was not one positive case (Luczak et al., 2001).

Assuming that the distribution of the acetaldehyde enzyme alleles in Chinese Americans has not greatly changed, many

nineteenth century Chinese had no easy way to get intoxicated. Alcohol made them sick. Consequently for those who found pleasure in intoxication, opium filled a niche that heretofore had no occupants.

The genetic explanation is perfectly compatible with the psychological, cultural, and economic accounts, but is different from them in that it identifies a unique feature of China, thereby making China's unique history with opium more understandable. Finally, it should also be pointed out that each of these accounts presumes a sizable population with leisure time on their hands and disposable wealth. Opium was a luxury and smoking opium to the point of intoxication typically takes at least two to three hours of time.

Summary

For millennia, opium was the herbalist and physician's most effective and celebrated treatment for medical disorders. In the seventeenth century this changed. Chinese abroad and then at home began smoking opium. The practice spread across all social strata; use turned to abuse; and government officials placed restrictions on the sale and use of opium, labeling opium a 'trap' and its users 'criminal' and 'gullible.' Smoking, a new form of self-administration, helped trigger the transformation of opium from boon to bane. However, inhalation was not a sufficient causal factor. During the eighteenth century, opium smoking could have become widespread in many places, yet only in China did opium smoking reach proportions that resulted in a thriving black market and government prohibitions. This was due to a unique combination of factors, including relatively large amounts of disposable wealth, relatively generous amounts of leisure time, cultural values that stressed private, sensory pursuits, a genetic predisposition that discouraged alcohol consumption, and weakly enforced prohibitions. European and British economic and political exploitation of China must have played a role also, but Western colonialism was worldwide, whereas the 'opium epidemic' was unique to China.

When Addictive Drugs Were Legal in the United States

Prior to the 1914 Harrison Narcotics Tax Act, addictive drugs, including heroin and cocaine, were legal in the United States. This proved fertile grounds for the patent medicine industry. Scores of companies marketed mixtures of alcohol, opiates, and cocaine, with colorful labels and grandiose claims. *Mrs. Winslow's Soothing Syrup* "soothed any animal or human," particularly colicky infants, and Dr *McMunn's Elixir of Opium* relieved "morbid irritability of body and mind." Those who had no local pharmacy to go to could send away to Sears Roebuck and other mail order companies for the drug of their choice, including morphine (which came with the promise that it would keep husbands home at night, away from the saloon). There are no data on actual sales, but on the basis of import records and historical documents, Courtwright (1982) has estimated the amounts of opium and morphine (which chemists had synthesized in the early nineteenth century) consumed by Americans over the years 1827–96. Consumption peaked in the 1890s. In this decade, Americans consumed about 3685 tons of opium each year. Thus, over the second half of the nineteenth century and for almost two decades of the twentieth, opiates were legal and not difficult to find in the United States.

Americans appear to have had as easy access to opium as did the Chinese. Indeed in China, opium was officially illegal, whereas in America patent medicines laced with opium were legal and popular. Nevertheless, opiate use in the United States remained well below the rates in China. Assuming widely accepted population estimates (400 million and 70 million people, respectively), opium consumption in China was approximately 0.2700 pounds per person, and in the United Sates it was approximately 0.0033 pounds per person. However, the per capita calculations overlook important differences in the two countries. By the second half of the nineteenth century, opium smoking in China was most common among laborers and rickshaw pullers. In the United States, smoking was but one form of opiate self-administration, and the demographic correlates were diverse, varying with the mode of consumption.

Laudanum Drinkers ('Opium Eaters')

Laudanum was the most widely used opiate. For millennia, it was the healer's most reliable antidote for coughs, pain, and distress. But in the nineteenth century, laudanum became a drug of abuse. Thomas De Quincey's famous memoir of addiction, *Confessions of an Opium Eater* (1821), featured laudanum, and physicians began to specialize in the treatment of laudanum 'inebriates.' According to reports from druggists, physicians, and newspaper reporters, laudanum users included, men, women, the aged, the young, suburbanites, urbanites, and even the very well-to-do (Brecher, 1972; Courtwright, 1982; Musto, 1973). Although it is often stated that most laudanum users were women from well-to-do families (e.g., Brecher, 1972), this claim may reflect a sampling bias. Women were more likely to go to a physician or clinic for help in dealing with laudanum addiction than were men, so that the physician reports may be biased (Ahn, 1996). However, that some laudanum users were wealthy and female was intriguing. Consequently, newspapers began portraying laudanum as a refined, sophisticated indulgence. For example, an 1881 editorial in the *Catholic World* labeled laudanum drinking an 'aristocratic vice' that is more common among the educated and wealthy, although the writer goes on to say that it spares no one (quoted in Brecher, 1972).

Although laudanum attracted all sorts, there was a common factor in how it was used. Laudanum was consumed in private, behind closed doors. As a result, laudanum drinkers were not perceived as a threat to public safety. Instead, they were perceived as ill or neurotic, and among physicians, they inspired a new medical specialty, the study and treatment of 'inebriation.'

Opium Smokers

In the third quarter of the nineteenth century, more than 250 000 Chinese men immigrated to the American West to work as laborers. They laid railroad track, dug tunnels through the Sierras, and scoured the earth for gold and silver. They were

poorly paid, ostracized by non-Chinese, and terrorized by vigilante groups and organized labor. In the labor camps and Chinatowns, opium smoking flourished. In contrast to laudanum drinking, it was a group activity that took place in discreet, hidden-away rooms ('opium dens'). A few non-Chinese Americans joined in. In contrast to laudanum drinkers, they had a distinct demographic profile. In newspapers of the day, they were described as 'evil' men, 'fallen' women – gamblers and prostitutes (e.g., Courtwright, 1982). No one would confuse laudanum drinkers with opium smokers.

Heroin Sniffers

In 1895 the Bayer Pharmaceutical Company began marketing a semisynthetic opium-based drug they called 'Heroin.' This was a made-up word that suggests the German word for heroic (*heroisch*). The ads bragged that when it came to suppressing respiratory symptoms, 'heroin had no equal.' This claim rested on fact. Heroin is much more lipid soluble than morphine, which allows it to enter the circulatory system and brain more rapidly. As a result, a given dose of heroin is about 10 times more potent than the same amount of morphine. As the morphine content of opium is about 10%, heroin is about 100 times more potent than opium. The Bayer managers also claimed that heroin was not addictive. They were not being purposely misleading. A few Bayer employees had been persuaded to try heroin. As is often the case with initial exposure to heroin, the experience was highly unpleasant. Bayer officials concluded that this ruled out addiction.

The intoxicating effects of heroin soon became known and sought out. However, little is known about the first generation of heroin users. The most frequently cited reference is an 'eyewitness' account by Pearce Bailey (1916), a physician and New York State public health official who specialized in 'defectives.' According to Bailey, 'heroin sniffers' were young men who hung out in gangs in East Coast urban centers. They had quit school, rarely worked, and were often in trouble with the law. For these young men, heroin functioned as a badge of identity, signifying rebelliousness, and disdain for conventional employment. At the end of his article, Bailey proposed that state officials relocate the 'heroin boys' to a rural setting and allow the restorative powers of agricultural work to do its magic.

Did Addiction Increase in Epidemic Proportions?

Given America's history of prosecuting drug use, it is reasonable to suppose that drug use grew at epidemic proportions prior to the passage of the Harrison Narcotics Tax Act. However, historians estimate that there were never more than 300 000 opiate addicts prior to 1914 (Courtwright, 1982; Musto, 1973). This implies an overall prevalence of less than half of 1% (0.0043). This is markedly less than even the lowest estimates for China in the same period (e.g., 2%). The pre-prohibition rate is also within today's rates. In the most recent and largest national survey (Conway et al., 2006), lifetime frequency of opiate dependence was 0.3% and in the Epidemiological Catchment Area survey of the early 1980s (Anthony and Helzer, 1991), lifetime frequency of opiate abuse and/or dependence was 0.7%.

There is of course much uncertainty about these estimates, particularly those from a hundred years ago. Historians have to rely on indirect measures, such as pharmacy sales and taxes on imported drugs. Today's researchers have the advantage of a scientific research tradition and well-funded projects that enlist the help of trained interviewers. Nevertheless, the old and new survey results are in rather close agreement. The simplest explanation is that the lifetime prevalence of opiate addiction in the United States at the end of the nineteenth century and the end of the twentieth century were not that different, somewhere between about 0.3% to perhaps 0.7%, and likely closer to the 0.3% mark. The broader implication is that legal restrictions were not the only curb on opiate addiction in the United States. In support of this point, opiate use and addiction peaked in the mid-1890s, well before the Harrison Narcotics Act.

The Response to Opiate Use in the United States

Although there is no evidence of an addiction epidemic prior to the Harrison Act, opiate use did elicit interest and concern among physicians, social reformers, and politicians. A number of physicians began to specialize in the study and treatment of addiction, the Temperance movement added opium addiction to their list of concerns, and legislators began passing laws to limit the use of opiates.

Physicians

In the late 1860s, a handful of physicians founded a new specialty, the treatment and study of 'alcohol and drug inebriety' or what we would now call alcoholism and addiction. They built treatment facilities, founded the American Association for the Cure of Inebriety in 1870, and in 1876 began publishing the *Journal of Inebriety*. The editor and contributors were physicians, and the one common theme of the published papers was that alcohol and opiate inebriety were diseases (Weiner and White, 2007). However, these early addiction specialists met stiff and eventually overwhelming opposition. As they put it, the claim that addiction was a disease was met with 'hysterical denunciations.' The prevailing view was that 'inebriates' got drunk or high because they wanted to not because they had to (Levine, 1978).

The Legislative Response to Opium Addiction

The Association for the Cure of Inebriety was at loggerheads with a powerful grassroots temperance movement. Concerned citizens, clergy, politicians, and many physicians joined forces to end drunkenness, addiction to patent medicines, opium smoking, heroin sniffing, and saloons. Their efforts won wide support. In 1906 President Theodore Roosevelt signed into law the Pure Food and Drug Act, which called for patent medicine manufacturers to label their bottles with the warning 'May Be Habit Forming' and a list of the amounts of opium, cocaine, and alcohol. According to Musto (1973), the labeling act reduced patent medicine purchases by as much as one-third. Then in 1914 came the legislation that transformed American drug use and set the terms for American drug policy ever since.

The Harrison Narcotics Tax Act limited the use of opiates and cocaine to the practice of medicine. The legislation did not mention addiction nor define medical practice, but focused on the regulation of trade. However, the justice department targeted all use except for the relief of pain in medical settings (Courtwright, 1982; Musto, 1973). Doctors who had been prescribing opiates to addicts stopped doing so, and with few exceptions (e.g., cough syrups containing small amounts of codeine) Americans could no longer buy opiates or cocaine at their local pharmacy. Indeed using opiates and cocaine without a prescription was now a criminal act. Drug users were arrested and sent to jail. In a sign of the times, the Association for the Cure of Inebriety stopped publishing their journal in 1914, and in a few years the medically staffed sanatoriums for the treatment of addiction were a relic of the past (Weiner and White, 2007).

The Consequences of the Harrison Narcotics Tax Act

Following the Harrison Act, laudanum drinkers and opium smokers all but disappeared. Heroin use persisted, but because it was illegal, it became even more closely tied to criminal activity. Criminal gangs took over heroin's distribution, adulterated it with inert substances, and raised prices. Users switched to injecting heroin in order to get the same kick that snorting had provided. Apparently, laudanum drinkers were unwilling to inject themselves with a substance that by weight was about a hundred times more powerful than opium. Street addicts now included repeat offenders who had committed serious crimes. Among the first to document the transformation of opiate use in America were Lawrence Kolb and A.G. Du Mez, physicians who worked for the Public Health Service and specialized in addiction. They characterized the demographic consequences of the Harrison Act in the following words (1924):

> addiction is becoming more and more a vicious practice of unstable people, who, by their nature, have abnormal cravings which impel them to take much larger doses that those which were taken by the average person who so often innocently fell victim to narcotics some years ago. Normal people now do not become addicted or are, as a rule, quickly cured, leaving as addicts an abnormal type with a large appetite and little means of satisfying it. (p. 1191)

Put another way, the middle-class laudanum drinkers disappeared, so that the remaining addicts were hardened versions of Bailey's 'heroin boys.'

Lessons

The American Experience

Although opiates and cocaine were legal and widely available in the last half of the nineteenth century and early twentieth century, there was no opium epidemic, as in China, and the prevalence of opiate use and addiction may have been about what it is today. The simplest explanation is that for most Americans intoxication was usually not a particularly desirable state. For instance, intoxication interferes with the business of life, particularly conventional activities, so that most of the time it would be impractical to take heroin or other intoxicating drugs. Second, opium smokers and heroin sniffers included a disproportionate number of individuals who were unemployed, undereducated, and involved in illegal activities. Thus, the claim that drug prohibitions turned addicts into criminals is at best a simplification of the facts. Third, antidrug legislation reduced drug use in those who by today's standards would have been considered addicts. However, the legislative effects were selective. The Harrison Act virtually eliminated opium smoking and laudanum drinking, whereas heroin use persisted. Events much later in the century reveal that these differences were not strictly a matter of heroin's powerful pharmacological actions. Quit rates for heroin addicts are about the same as for other drugs (Anthony and Helzer, 1991; Stinson et al., 2005), and the correlates of quitting include the ordinary pressures of adult life, such as economic well-being, familial responsibilities, and the opinions of others (Waldorf, 1983), which is also the case for other drugs (e.g., Heyman, 2009).

The Transition from Use to Abuse

Laboratory psychopharmacology research shows that the behavioral effects of psychotropic drugs invariably reflect the setting and individual differences. For example, in rat studies the same dose of amphetamine can either increase or decrease reinforced lever pressing as a function of differences in the animals' reinforcement history. The history of the transition from opiate use to opiate abuse involves the same sort of contextual influences. Americans had access to opiates that were 10 (morphine) and 100 (heroin) times more potent than the opium available in China, yet the rates of opiate addiction in China were 10–20 times higher than in the United States. Conversely, the prevalence of alcoholism is substantially lower in China than in the United States, yet the United States has put more road blocks in the way of drinking (e.g., Xiang et al., 2009). Thus, to make sense of addiction it is necessary to take into account characteristics of the setting (e.g., legal prohibitions and cultural traditions), characteristics of the individuals (e.g., the genetics of drug metabolism), and characteristics of the pharmacological experience (e.g., the transition from drinking tinctures of opium to smoking opium).

Abstract

Public opinion is a contested concept. The nature of the 'public,' the political concepts and values that constitute 'opinion,' and the process whereby public opinion is formed are all matters of debate. In the dominant view, the public is a composite of individual citizens and opinion consists of the beliefs that are subjectively associated with an attitude object. The process of public opinion formation therefore revolves around individuals. Empirical research adopting this view focuses on information processing and thus examines the role of perception, reasoning, and memory on attitude formation. The conclusion is that people generally do not attend to, understand, or care about politics. What attitudes they express are typically unstable, inconsistent with one another, and do not reflect any overarching ideological point of view. Public opinion formation is also understood from three other perspectives. The first retains a psychological focus but takes a more holistic view of political meaning and examines qualitative differences in how individuals represent, understand, and judge experience and information. The second shifts the focus from individuals to discourse and considers how political concepts and values are constructed through democratic deliberation. The third perspective views publics in holistic terms and argues that public opinion is an irreducibly collective phenomenon, one that is shaped by commensurately large-scale social forces.

The concept of 'public opinion' has been debated across disciplines and centuries. At issue is the nature of the 'public,' the political concepts and values that constitute 'opinion,' and the process whereby the public opinion is formed. One key point of division is epistemological: whether to view political meaning as an aggregate or a structured whole. According to the aggregative view, political meaning consists of a set of elements (representations of experience), which are related to one another either through passively learned association or through active mental calculation. The alternative view suggests that political meaning is constructed. How it is constructed delimits the nature of the representations that may be formed and the quality of the associations or calculations that can be made.

A second divide is more explicitly political. The issue here is where to locate public opinion and, by implication, where to look in order to explain it. One view assumes the public is a composite phenomenon, an aggregate function of its individual citizens. In this view, political meaning and value are attributes of individuals. Analysis therefore focuses on the qualities of cognition and, in this light, how individuals process the experiences and social influences to which they are exposed. The opposing view presumes that the public is a collective entity, a corpus of its own. Here political meaning and value are emergent properties of the collective. They are viewed as essentially cultural phenomena and are explained with reference to large-scale social forces.

The Mainstream Perspective: Publics and Meaning as Aggregates

Although these debates remain central in contemporary political theory, a consensus emerged in the empirical study of public opinion formation. Its basic contours were defined by Allport's (1935) seminal discussion of attitudes, the Yale persuasion studies (Hovland et al., 1953), and Converse's (1964) analysis of political belief systems. Although pursuing different topics from different disciplinary perspectives, the research is oriented by the same political and epistemological vision: the public is an aggregate of its individual citizens, and political meaning is a matter of calculated or learned associations among representations and preferences. In this light, the formation of public opinion is understood to be a process that revolves around individuals. It begins with their exposure to politically relevant experiences and information. Each individual processes this information, thereby coming to a judgment that yields an attitude. The attitudes of different individuals are then aggregated, either through informal interactions or more formal mechanisms, such as elections or opinion polls.

For the most part, this research effort has focused on the second step in the opinion formation process, the social psychology of how individuals process information (either from direct or indirect experience) when forming an attitude. The critical outcome or dependent variable is an attitude. Typically, this is defined as an individual's overall evaluation of an object with some degree of favor or disfavor. In this view, an attitude consists of three types of elements: cognitive (beliefs); affective (emotions or feelings); and behavioral (intent to act). These elements can affect one another. While they are usually consistent, they may not be. Attitudes are also related to one another.

In a way that has important consequences for attitude strength and stability, this interattitudinal structure may vary with regard to its elaboration, its coherence, and the degree to which it has a hierarchical structure. A central aim of the research is to examine how different conditions (both situational and dispositional) affect the processing of information and thus the resulting attitude. The research is designed on the presumption that all individuals operating under similar conditions will process information in the same way. Consequently subjects' responses are aggregated, and inferences are made regarding how the 'average' person will form, maintain, or change their opinions under the conditions examined.

Adopting this general framework, a wide variety of competing theories or models of public opinion formation were presented from the 1950s to the 1980s. Some posit a rational, almost logical, integration of information. A prominent example is the value-expectancy model (e.g., Fishbein and Ajzen, 1975). According to this model, an individual forms or changes an attitude by reviewing their beliefs about the attitude object. A weight is assigned to each belief by multiplying its assessed value by the probability that the belief correctly pertains to the object in question. The expected values of all the beliefs are then averaged, leading to an overall attitude or judgment being formed.

Other models accept the basic features of such rational computational models but focus more on considerations of memory and its effect on what beliefs will be considered. The suggestion here is that an individual may have a diverse set of contradictory beliefs or affects associated with an attitude object. Situational and internal cues affect which of these beliefs is likely to be remembered on any given occasion. Consequently, although individuals may process beliefs rationally, the ways in which memory functions will bias which beliefs are processed and therefore what judgment is finally made. How mass media prime candidate evaluations and the apparent instability of political opinions are readily explained in these terms (e.g., Zaller, 1992). On-line processing models of political candidate evaluation de-emphasize the importance of recall (e.g., Lodge and Steenbergen, 1995). In this view, individuals do not judge an object by recalling all relevant beliefs. Rather, they simply remember their prior evaluation of the object and adjust this in light of the new information provided. While this information may then be forgotten, the overall assessment is carried forward when further judgment is required.

Other models of information processing suggest that judgment is more irrational. One example is the family of cognitive consistency models which suggest that individuals relate objects to one another, not only on categorical or logical grounds, but also on the basis of evaluation or feeling. A particularly influential extension of this is Tajfel's (1981) analysis of the consequences of group identification. His research suggests that a person's desire to maintain self-esteem (positive evaluation) and their negative identification with an out-group (categorical link) will result in negatively biased evaluations and behaviors toward that group. Following a learning theory tradition, other research demonstrates how regularly pairing an unconditioned stimulus (an object already valued positively or negatively) with a conditioned stimulus (an object not valued) will shape the subsequent evaluation of the condition stimulus.

In recent years, there has been a shift to more eclectic dual processing models of attitude formation. Self-consciously integrating earlier conceptions, these models suggest that different processes will operate under different conditions. Two types of processes are distinguished. Central processes, such as the value expectancy model, are relatively demanding and involve the evaluation of relevant arguments and information. Peripheral processes are less demanding than central processes and include classical conditioned responses, reliance on peripheral situational cues (e.g., physical attractiveness of the source), or the use of simple heuristics (e.g., experts know what they are talking about). The focus of this research is to discover (1) what conditions foster what type of processing and (2) how different kinds of processes affect attitude formation under different conditions. This has led to a reconsideration of the early research on the persuasive effect of source variables (e.g., credibility, expertise), message variables (e.g., argument quality, personal relevance), recipient variables (e.g., prior attitude, personality), and context variables (e.g., distractions, audience reaction). The net result is a more complex and contingent understanding of how attitudes are formed, sustained, and changed (Petty and Wegener, 1998).

Political scientists have drawn upon these models in their attempt to understand opinion formation in mass publics. Thus they have focused on who is presenting what information (the agents of socialization – family, workplace, school, social groups, and the mass media), to whom, and with what effect on individuals' judgment and knowledge of political leaders, issues, and events. The research on agent effects on opinion formation suggest that whereas the family is not as influential as initially believed, it does provide individuals with one of their most enduring characteristics: their political identity. Supporting early survey research, contemporary work indicates that group identification can influence powerfully individuals' attitudes toward issues, especially those emphasized by the group. Research also indicates that the mass media, while not the powerful persuader it was initially feared to be, nonetheless is able to affect people's sense of political priorities and to prime the specific considerations they may bring to bear when judging a particular issue or candidate.

In the case of knowledge and sophistication, the evidence suggests overwhelmingly that the vast majority of people have little accurate information about political leaders, current legislation, or foreign affairs. Nor do their judgments reflect much sophistication or consideration. What attitudes they express do not cohere in any apparent ideological fashion, nor are they particularly reliable over time. Even slight changes in how questions are posed can produce different attitudinal responses. Some studies do show correlations between apparently abstract and more concrete attitude items. This result is interpreted to suggest people do base particular judgments on more abstract core values. However evidence from open-ended interviews indicates that whereas a few people do think about politics in this deductive way, most do not. Their responses are generally ill-considered, unjustified, and readily changed by new considerations that pop to mind. Overall, the evidence suggests that citizens lack the information, understanding, or considered judgment typically called for in democratic political theory.

Alternative Direction: Constructivism, Discourse, and Collective Publics

Questions have been raised regarding the basic assumptions orienting this dominant approach to the study of public opinion. The results of open-ended interviewing have sparked an increasing interest in taking a more constructive, holistic view of political thinking. This has lead to a renewed interest in constructivist psychologies that consider basic differences in how individuals reason (e.g., Rosenberg, 2002). In this view,

how an individual thinks about social or political events will determine the kinds of interrelationships and the kinds of representations (and interests) they can construct. Moreover, different individuals may think in qualitatively different ways.

For example, some people tend to focus on a simple causal or categorical relationship cued by the situation when formulating an understanding, and they draw primarily on social convention or group interests to make their judgments. Other people focus on only the concrete contours of the immediate situation and draw primarily on present feelings to make a judgment. Still others infer quite abstract issues that are only implicit in the situation and judge them with reference to some notion of the general interest or abstract principle. Contrary to the common assumption of the 'average citizen,' this work suggests that people may differ significantly, both in how they are affected by the same social influences and in their capacity to respond to different kinds of institutional regulation.

This interest in reasoning dovetails with the dissatisfaction expressed by some political theorists regarding representative democracy and its emphasis on electoral mechanisms of preference aggregation. Instead, they advocate more deliberative forms of democracy that require individuals to cooperate in the generation and resolution of political issues (e.g., Habermas, 1996). In this light, considerations of the requirements of citizenship shift. Rather than personal judgment, the focus is on cooperation with others in order to come to common understanding and judgment. This involves taking the perspective of another, relating it to one's own, and then critically considering both. The latter not only entails compromise, but the self-conscious construction of new positions that incorporate and go beyond the original ones. Research motivated by these concerns seeks to determine how differing institutional arrangements impact on deliberation and with what effect on the collective judgments that ensue. It does so by eschewing a focus on individuals in favor of a direct examination of the quality of deliberations themselves and the social representations and group opinions they produce.

Finally, there is renewed interest in a more holistic, constructivist view of the public. Rejecting what is referred to as methodological individualism, social theorists have argued that consciousness and meaning making are essentially collectively structured phenomena that are best thought of as a culture or mode of discourse. Some view culture as singly structured and coherent, and others argue that it is essentially an arena of conflict. However, all agree that the individual's understanding is a generally poor reflection of a larger social process and an inappropriate object of inquiry. In this more sociological vision, changes in public opinion reflect changes in the underlying structure of collective meaning. Examples include the shift in public discourse from appeals to the sacred to reasoned argument regarding the profane, or a population coming to imagine itself as a nation (e.g., Anderson, 1991). Such changes are explained with reference to collective forces such as the form of the relations of production, the mode of information, or a new geographical positioning of a population. With such changes, alternative forms of institutional regulation become possible (e.g., rule by personal power vs rule by law) and new kinds of political values are constructed (social tradition vs principled critique). The challenge to this line of inquiry is to develop an empirical methodology as sophisticated as the theorizing.

Oppression

Katherine van Wormer, University of Northern Iowa, Cedar Falls, IA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article considers the root causes of oppression from social work's biopsychosocial framework, looking at biological, psychological, and social theories of oppression and explores types of oppression as delineated in the literature. Macro- and microforms of oppression are considered. From a macro- and Marxist perspective, oppressive aspects of economic globalization are discussed. From a micro-perspective, attacks on individuals on the grounds of personal or cultural difference are briefly considered. The second part of the article focuses on antioppressive theory and antioppressive practice as concepts associated most closely with the social work profession. Finally, examples of antioppressive practice are presented.

Introduction

Why is there oppression in the world? Why is there a tendency for one group to oppress another? What do scientific theories say about the basis of this social phenomenon? Although no definitive answers to these age-old questions are possible, and scholars disagree about the causes if not consequences of oppression, these are important issues to explore. In this article, I consider definitions of oppression, explanations about its prevalence, and implications for practice.

Defining Oppression

There are various definitions of oppression (Dominelli, 2002). However, because social workers are concerned (at individual and policy levels) with the victims of oppression and its prevention, define oppression as in the *Social Work Dictionary*:

> Oppression [is] the social act of placing severe restrictions on an individual group, or institution. Typically, a government or political organization in power places restrictions formally or covertly on oppressed groups so they may be exploited and less able to compete with other social groups. The oppressed individual or group is devalued, exploited, and deprived of privileges by the individual or group who has more power.
> (Barker, 2003: p. 307)

Devaluation, exploitation, and privilege are key concepts in it, which are inextricably linked to the phenomenon of oppression, which exists in all societies, and has probably done so throughout history. Attempts to eradicate oppression in society are relatively new, and the focus may be on one group to the neglect of another. For example, in the United States and Northern Ireland during the 1960s, while the civil rights movements brought a focus on discrimination and denial of human rights to minority groups on the basis of race and religion, respectively, the denial of women's rights were largely ignored. In the US, the forces that brought about freedoms for the groups in question (blacks and other minority groups) ultimately led to the feminist movement and social changes that extended across the Western world in subsequent decades.

The Nature of Oppression: What Are the Root Causes?

Iris Young's (1990) formulation of five categories of oppression is helpful to social workers seeking to understand the oppressions faced by the people with whom they work. The five forms of oppression included in her model are exploitation, marginalization, powerlessness, cultural imperialism, and violence. Drawing on Young's work, Dorothy Van Soest (2008) delineates the following key characteristics of oppression: bestowing power and advantage on those regarded as the norm and denying power and advantage to others who are seen as different; and using ideology and violence or the threat of violence to retain their privileges. Society's institutionalization of the norms of oppression and the invisibility of members in oppressed group are additional characteristics. Privilege is the flip side of oppression, oppression cannot exist in the absence of privilege, and those who have privilege may not even be aware of it (Robbins, 2011). With in-groups and out-groups in a society, what is oppression in one context may be privilege in another (Samuels and Ross-Sheriff, 2008).

These basic details about the nature of oppression challenge social workers, social scientists, and other students of human behavior to take a holistic approach to understanding privilege and oppression at the macro-, structural level, as well as in seeing how they are played out at the micro-, personal level. Samuels and Ross-Sheriff illustrate this through adopted biracial children brought up in middle-class homes. Although members of families with access to material and social resources and privilege, they may still encounter racial discrimination as blacks in external social settings.

Taking a biopsychosocial perspective in *Confronting Oppression, Restoring Justice*, van Wormer et al. (2012) consider theories of oppression provided by biologists, psychologists, and sociologists. These perspectives differ on the particular forms of oppression emphasized and the disciplines represented. Evolutionary biologists, e.g., stress genetic and instinctual components and focus on aggression in nonhuman and human behavior (Green, 2001; Wilson et al., 2012). Within each species, strong animals dominate and suppress the others; these survive and have most of the offspring. Similarly, Kurzban and Leary (2001) argue from a survival-of-the-fittest rationale that the social exclusion of people with disabilities among humans today is a throwback to an evolutionary past

when intergroup competition was fierce, exclusion and even elimination of 'unfit' members of the group would have enhanced the group's survival. A very different biologically based theory is presented by Cunningham et al. (2004). These researchers conducted laboratory experiments that suggested racism was an unconscious negative fear response to images of people who look different from one's social circle.

In the psychological realm, there are seemingly natural tendencies to blame the victim (Ryan, 1976; van Wormer et al., 2012). Such victim blaming can be considered a form of oppression. People who have lost their homes, persons who are chronically ill; those who have been raped and beaten – all are likely to be held at least partially responsible for their fate by the general public and their own families. Ryan (1976) described the phenomenon of blaming the victims of misfortune as a generic process applied to almost every social problem that exists. Victim blaming occurs when the downtrodden or 'underdogs' of society are held responsible for creating their own hardships. This can be understood as a psychological defense mechanism, as a way for people to cope with the suffering of others – by turning away from it. A related theoretical explanation is the theory of displaced aggression, which describes situations in which a person transfers his or her feelings of anger from one source to another, weaker source (see Allport, 1981/1954), e.g., an entire people may redirect their anger about a bad economy onto a marginalized group such as a racial or ethnic minority. This introduces the social realm. Before expanding the unit of analysis, I consider the psychological impact on the person who is victimized in these ways. Internalized oppression, or aggression turned inward, is often the end result. As African-American bell hooks (1993) states:

> Black people are indeed wounded by forces of domination. Irrespective of our access to material privilege we are all wounded by white supremacy, racism, sexism, and a capitalist economic system that dooms us collectively to an underclass position. Such wounds do not manifest themselves only in material ways; they affect our psychological well-being.
> (p. 11)

Social scientists focusing on conflict consider oppression as structural, with causes to be found in society as a whole (Corrigan and Leonard, 1978; Lundy, 2011; Mullaly, 2007; Vickers, 2012). This perspective, described and categorized by Malcolm Payne (2005) as radical and socialist-collectivist, is also consistent with social work values and ethics. In their change efforts, many social workers come into conflict with powerful forces in society that resist progressive change. This perception of society as torn by conflict rather than united in consensus had its origins in the teachings of Karl Marx. Today, radical sociologists and social workers highlight the powers of corporations and big banks in preserving the status quo and maintaining their own economic interests at the expense of people excluded from this power structure (Corrigan and Leonard, 1978; Lundy, 2011; Mullaly, 2007; Reisch, 2013; Vickers, 2012). Corporate control of the media portrays images of 'the just society' with great effectiveness and can spread conservative ideology consistent with the vested interests of rich and superrich people.

Other representations of this school of thought include David Gil (1998) who revealed how to confront injustice and oppression, Anne Bishop (2002) who focused on becoming allies of various oppressed groups in effecting social change, and Bob Mullaly (2007, 2010) who produced influential theories about structural social work in Canada.

Biology, psychology, and sociology provide insights into the nature of oppression with the most relevant from an anti-oppressive perspective being the radical sociological or structural approach. Oppression theory, as Susan Robbins (2011) suggests, is derived from several disciplines and shares conceptual frameworks with sociological conflict theory, critical social theory, feminist theory, and empowerment theory, radical economics, and the interdisciplinary approaches of radical social policy and critical theory. All of these have contributed significantly to understanding the nature of oppression. Marxist concepts about the interlocking systems of privilege and domination, exploitation of powerless people by rich ones who get richer, and alienation of workers, are infused in the writings of oppression theorists. Conventional social work seeks to preserve the prevailing social order (Mullaly, 2010).

Intersectionality

On the American continent, evidence of yesterday's oppression appears in the jolting words of bell hooks (2009), who recently returning to her roots in the hills and hollows of Kentucky, said:

> I was a little girl in a segregated world when I first learned that there were white people who saw black people as less than animals. Sitting on the porch, my siblings and I would watch white folks bring home their servants, the maids and cooks who toiled to make their lives comfortable. These black servants were always relegated to the back seat. Next to the white drivers in the front would be the dog and in the back seat the black worker. Just seeing this taught me much about the interconnectedness of race and class.... I was the girl they [the workers] did not see, sitting in the swing, who felt their pain and wanted to make it better.
> (pp. 148–149)

Much of the discourse about oppression addresses a dichotomous relationship between specific dominant and subordinate groups that assumes individuals must fit neatly into one group or the other. By not considering the intersections of multiple roles and identities, arguments of comparison about whose oppression is worst can prevail. The end result is that oppression can then be blamed on just one group (e.g., white working-class men) rather than considering power within its social and political contexts or analyzing how oppression is maintained. Patricia Hill Collins (1999) locates the solution to problems of 'difference' in what she, and others before her, have termed *intersectionality*. In oppression theory, this term is used to address the experiences of people who are subjected to multiple forms of oppression and domination. This multidimensional lens, facilitates understanding of how membership in a marginalized group like the female gender, combines with other key social characteristics

and statuses related to oppression, such as race or ethnicity, to produce a synergistic or multiplying effect that is stronger than the sum of the separate categories of difference. National origin, culture, religion, caste or class, age, gender identity and sexual expression, (dis)ability, and/or having the status of exconvict among others are categories that in combination can subject people to heightened levels of discrimination. Devah Pager's experimental research on responses to employment applications beautifully illustrates the point. Pager (2003) and Pager et al. (2009) tested the concept of intersectionality in their research on the low-wage labor market. Their research provides evidence that the effect of race can be magnified by additional factors, e.g., criminal history. Within social work, intersectionality is increasingly used in journal articles on minority issues and social work practice textbooks. Hulko (2009) discusses the theoretical paradigm of intersectionality relating to interlocked oppressions involving women. Writing from a feminist standpoint, Mehrotra (2010) similarly discusses the impact of intersectionality on South Asian women who identify or are identified as lesbians. In their text, *Multidimensional Contextual Practice*, Guadalupe and Lum (2005) emphasize how membership in more than one marginalized group at a time has a compounding effect on one's vulnerability to discrimination.

Antioppressive Theory

Antioppressive theory is widely used in all the English-speaking countries other than the United States. American social work professionals tend to draw upon an empowerment perspective, which also is concerned with power arrangements in society when working through the system to effect social change (Payne, 2005). Antioppression can be likened to an empowerment approach through its attention to power differentials in worker/client relationships and in helping clients gain control of their lives (see Humphries, 1996). Practitioners, as Payne (2005) suggests, can avoid oppressing (thereby empowering) clients through partnership, client choice, and seeking changes in the agency and wider systems that adversely affect clients. Both orientations are about minimizing power differences in society and maximizing the rights to which all people are entitled (Dalrymple and Burke, 2007; Dominelli, 2002). Both approaches seek the eradication of oppression at multiple levels of social life: the personal, interpersonal, structural, and cultural (Mullaly, 2010; Robbins, 2011). Empowerment social workers operate more at the individual and small-group levels from a strengths-based perspective, while antioppressive social workers are more critical of the status quo.

Dominelli's (2002) articulation of *Anti-Oppressive Social Work Theory and Practice* stresses the holistic role of social work within a rapidly globalizing economy, and has been influential in the profession, especially in the UK, Australia, and Canada. Central to her theoretical approach is an understanding of the deleterious effects that macro-level economic forces can have on peoples' daily lives. Dominelli's approach is multidimensional – socioeconomic, political, cultural, spiritual, and environmental, embedded in social justice and human rights, and argues for oppression being tackled at both the individual and/or interpersonal level and the structural one simultaneously.

Another major contribution to the antioppressive literature is the structural model introduced in Mullaly's (2010) *Challenging Oppression and Confronting Privilege*, where he describes antioppression as a starting point from which social workers can tackle oppression and discrimination. Structuralism and antioppressive perspectives are the dominant ones taught to Canadian social workers. The Canadian Association of Social Work Education, like its British counterpart, requires that Canadian schools of social work demonstrate their commitment to social justice and antioppressive social work in their curricula (Mullaly, 2010).

Lundy (2004) has built on Mullaly's ideas to develop the antioppressive conceptual framework and lay out concrete social work practice skills for individual, group, and community interventions. Using a structural approach, Lundy emphasizes human rights and views capitalism as the fundamental cause of the social and economic injustice that poor people experience. Within the context of the privatization of social services and erosion of social welfare programs, social workers are in precarious positions as they try to abide by principles of social justice.

Antioppressive Practice

Antioppressive theory, developed through the ranks of progressive practice and social action in the feminist and black activist movements, provides "an important explanatory base for action" (Payne, 2005: p. 13). Practicing from this perspective, social workers avoid blaming the victims of social problems, address the systemic nature of oppression, and rely on strategies such as consciousness raising, advocacy on behalf of marginalized groups, and community organizing for direct action. Antioppressive practitioners are critical of conventional social work practice and organizational failure in confronting unjust social systems. Van Soest (2008) challenges social work "to uncover, make visible, expose, and oppose oppressive relationships and systemic power arrangements that give privilege and advantage to one group over another" (p. 323). Ferguson and Lavalette (2006) urge that social workers move toward 'a social work of resistance' (title page).

The belief that personal troubles often stem from political sources is integral to the belief system of radical and antioppressive social work. The contribution of highlighting awareness that the 'personal is political' was originally made by feminist social workers who focused on services for women that were empowering and based on understanding that their individual problems were often systemic rather than personal (Dalrymple and Burke, 2007; Dominelli, 2002). Antioppressive social work practice has a rich history, as Dalrymple and Burke suggest. The teachings did not just emerge from the writings of academics but were a product of the real struggles of social workers in daily practice. Their struggles were not only against oppression of marginalized groups within society, but also against those elements of social control engrained within mainstream social work practice and reflected in the organizations where practitioners worked (Dominelli and McLeod,

1989). Contemporary antioppressive practice, as Dalrymple and Burke (2007) and Dominelli (2002) note, occurs within the context of globalization and the widening gap between rich and poor people linked to the neoliberal trends toward privatization of the social welfare state. Carniol (2000) articulates this position well:

> For social workers who engage in anti-oppression practice, there is a strong connection between, on the one hand, providing individual assistance to people belonging to disempowered groups, and, on the other hand, working with social movements connected to these disempowered groups. By linking these two ways of working, social service providers are challenging social services from the ground up. We are reframing 'private' problems as public issues.
> (p. 115)

To effectively confront oppression and injustice, social workers need an awareness of the forces, including psychological and structural factors, involved in their perpetuation. Such awareness in conjunction with a transnational perspective is essential for citizens to create a countervailing force to corporate power and unregulated capitalism. 'Think globally, act locally', as the environmentalists say (see Oberst, 2013; Winograd and Hais, 2009).

Global Forces of Oppression

How is it possible, Michael Dover (2008) asks, to overcome racism and other forms of oppression without fundamental changes to the system of capitalism? His discussion of worker exploitation and dehumanization is timely in considering the impact of global market capitalism at every level of the social structure because it hits hardest economically disadvantaged individuals and devastates most, low-income nations of the Global South with economies intertwined with those of the Global North. A study of the principles of global economics and free trade is thus an aspect of social work education that can no longer be neglected. For contemporary writings by social work academics on the impact of economic globalization, see Dominelli (2010), Ferguson and Lavalette (2006), Karger and Stoesz (2013), Link and Ramanathan (2011), and Reisch (2013).

Economic globalization encourages a skewed distribution of wealth, and wealthy people can access capital to invest in profitable enterprises. Access to money held by major US corporations brings with it political clout and control of elections as politicians depend on corporate finance for their campaigns. This is economic privilege to an extreme degree, and legally sanctioned recently by the US Supreme Court in *Citizens United v. Federal Election Commission* (2010). This decision allowed billionaires, corporations, and labor unions to spend unlimited sums of money on advertising that demands the defeat of individual candidates whose policies they oppose. At the same time, current US policies create tax breaks for rich people while increasing restrictions for welfare recipients and people facing unemployment. Privatized health care policies ensure continued high profits for pharmaceutical and health insurance companies; and the political clout of these corporate companies is enormous (Karger and Stoesz, 2013). In competition for government funding, between social services and corporate interests, the corporations generally win (Karger and Stoesz, 2013; Reisch, 2013). The implications for social work are significant.

At the global level, unrestricted capitalism has failed to raise the well-being of those in poverty, as Link and Ramanathan (2011) suggest, because the market has been manipulated by corporations. Competition, therefore, does not flow freely. Companies like Enron and Monsanto manipulate, pollute, and exploit for the sake of immediate profits at the expense of long-term gains. In the absence of tight regulation, corporate monopolies such as Monsanto, which produces genetically engineered seeds, can enforce policies to eliminate competition and name their price (van Wormer et al., 2012). Additionally, corporations, by moving their factories to the Global South engage in worker exploitation as far as is politically feasible. Social workers have important roles to play in terms of advocacy on behalf of individual workers (Link and Ramanathan, 2011). Collectively, social workers can organize for legislative protection of these workers' health and safety (see www.statepolicy.org to review social workers current efforts to influence US health and safety policies).

Social Work Contributions

Working globally, social work practitioners and academics produced a landmark document, the *Global Agenda*, following 3 years of collaborative initiatives undertaken by three international organizations, the International Federation of Social Workers, International Association of Schools of Social Work, and International Council on Social Welfare. The *Global Agenda* highlights the appalling conditions shaping human lives in a world that fails to hold to account market forces and enforce international standards for labor. These "have damaged the health and well-being of peoples and communities, causing poverty and growing inequality" (IASSW, 2012: p. 1; ICSW, 2012: p. 1; IFSW, 2012: p. 1). According to the *Global Agenda*, human rights are in danger worldwide (p. 1), and some aspects of economic globalization have had especially negative consequences for indigenous and First Nations peoples (p. 3). Recognizing these challenges, the *Global Agenda* pledges a commitment to focus on the following areas: "promoting social and economic equalities; promoting the dignity and worth of peoples; and working toward environmental sustainability" (p. 1).

An encouraging development took place in the United States, when the Council on Social Work Education (CSWE) (2008) issued its revised Educational Policy and Assessment Standards. The new standards placed a major stress on the teaching of concepts related not only to diversity, but also, human rights, oppression, and intersectionality. The social work curriculum was also expected to emphasize the global interconnections of oppression and cover "issues of power, privilege, and economic dominance" (p. 5).

Through the incorporation of theories of oppression, this educational revision implies a pronounced change in the focus of the standardized social work curriculum. The shift is from race to racism, sex to sexism, ethnicity to ethnocentrism, and

oppressed to oppressor. This shift is far more radical than that a quick reading of CSWE's (2008) revised curriculum standards would indicate. The new focus is structural, and on societal practices that perpetuate oppression rather than on teaching about diversity and cultural differences. This shift is consistent with social work values of social justice and nondiscrimination, and preparing students to become change agents. It is too early to tell what actual effects this curriculum change will have on social work in the USA long-term but it is an educationally significant development.

Besides preparing social work students for roles that many will play as therapists in social services agencies 'to help people help themselves', social work educators also prepare future generations to participate in policy making, as earlier generations have done. The social work curriculum emphasizes knowledge of the law in many countries, and in some such as the United States, social welfare policies are strongly emphasized. These enable students to face, "the daunting task of translating that understanding into actions designed to facilitate social change for social justice" (Van Soest, 2008: p. 347).

In the belief that policy and practice are inextricably linked, van Wormer et al. (2012) have introduced an antioppressive policy analysis model to guide social work class projects. The model leads students to discover solutions to problems that have been successfully applied elsewhere and to appreciate the many obstacles that they will encounter in introducing policy changes. A secondary goal of the exercise is to show that social workers and other helping professionals have vested interests in maintaining control and power, that for those employed in the field of social work, the 'personal is political.' Because research has shown that social work students have problems in recognizing the strategies of dominance and control are used to defeat progressive change, this exercise can be highly instructive. When tackled from an antioppressive perspective, policy analysis links the theory of oppression to policy practice.

Antioppressive Practice: Call to Action

Organizational constraints can turn antioppressive practice into a theoretical construct, or way of thinking, rather than actual practice. As social workers' belief-systems influence their professional behavior, familiarity with basic theories of oppression is a starting point for progressive policy practice. Social work practitioners and academics often occupy subordinate roles within their own agencies that require them to carry out policies with which they disagree. Agency and government policies can be oppressive when implemented in practice within a conservative setting and run according to a business model. What do social workers do then? They can quit their job or transfer to a different department; they can work within the system to change the system; they can go outside for influence, perhaps even become a whistleblower; or they can find ways to get around or even defy the most harmful aspects of the policies they are supposed to enforce. In the UK, e.g., the forced removal of unaccompanied minor asylum seekers when they reach adulthood at age 18 poses irreconcilable moral dilemmas for social workers (Wright, 2012). Social work values and ethics inform social workers in conflicts involving government legislation that their first duty is to the client. American social workers face similar situations because immigration is becoming increasingly criminalized and forcing agency employees to discriminate against undocumented clients (Furman et al., 2012).

Nzira and Williams (2009) tackle this common ethical dilemma. "Even if we feel we cannot have great influence over cultural or structural forces" Nzira and Williams (2009) advise, "we can strive to be personally antioppressive toward those we meet" (p. 38). Antioppression does not mean treating everyone the same but allowing for individual differences (Dalrymple and Burke, 2007; van Wormer et al., 2012). At the interpersonal level, social workers can engage in an antioppressive practice that is active and thoughtful. In working with people of different cultures, acquiring some knowledge of culture, language, beliefs, and likely experiences of the person can help put them at ease, show respect, and, if necessary, adopt an advocacy or support role based on partnership with service users and mutual learning.

To 'act locally', policy makers, helping professionals, and advocates who care about ending poverty and oppression need to develop skills and abilities to enable them to step forward as change agents. Activists can learn techniques of organizing through the Internet mobilization, regional teach-ins, and use of the alternative press to produce tangible results (see Haynes and Mickelson, 2009). Social workers engage in grassroots organizing on behalf of deprived groups including women living in countries where their rights are unprotected, indigenous populations, and preserving the physical environment from which all life flows. A new consciousness is promoting the protection of environmental and human resources, from Southeast Asia to the Americas. This consciousness is related to antioppressive approaches in several ways. Dominelli's (2012) *Green Social Work* reveals the connections between radical social work's values of solidarity and equality, and the questioning today's dominant model of economic development. Green social work is explicitly political, and the "values of antioppressive social work can become useful tools in mobilizing people to care for the environment" (Dominelli, 2012: p. 131). (See Gray et al. (2008), for indigenous approaches to the environment and a perspective that is consistent with antioppressive principles; and Besthorn and McMillen's (2002) article drawing parallels between the oppression of women and the oppression of nature.)

The Occupy movement, according to the *Huffington Post*, is appropriate for social workers who witness firsthand the connection between economic stability and physical and mental well-being (Jeltsen, 2011; Mason, 2012). As Mason (2012) states, social workers can learn from the Occupy Wall Street movement to shift their attention from concerns with individual minority groups to economic injustice and the need to alleviate gross economic inequalities.

Members of the Social Welfare Action Alliance (SWAA), to which many social workers belong, are actively involved in the national convergence of training, education, and action. Their goal is to train 100 000 people across the country in sustained, nonviolent direct action to expose the injustices of the moment

and demand change from those responsible (Johnson, 2012). SWAA members regularly organize rallies and teach-ins that reveal how the United States violates the United Nations Universal Declaration of Human Rights. The Kensington Welfare Rights Union (KWRU), affiliated with SWAA, develops leadership from the ranks of poor people to provide housing for homeless people. This organization uniquely links the civil rights movement with international human rights and uses civil disobedience is a tactic to house homeless people in abandoned dwellings in the Kensington neighborhood of Philadelphia. An internship program at the University of Iowa School of Social Work offers an immersion experience for social work students to learn about macro-level work from the KWRU in North Philadelphia (van Wormer et al., 2012). The documentary film, *Living Broke in Boom Times*, available at New Day Films, provides commentary by key activists in the movement.

Another movement that draws on human rights to combat oppression internationally is a form of restorative justice, e.g., Truth and Reconciliation Commissions (Androff, 2013; Stauffer, 2012) that promote healing through public testimony by the survivors of systemic oppression of minority groups through persecutions, war, and genocide (Androff, 2013). Such Commissions have been organized in South Africa, following apartheid; Timor Leste (formerly East Timor) at the end of a brutal occupation by Indonesia; and Canada to repair damage done to First Nations children, who having been forcibly removed from their homes and families, were placed in boarding schools and abused. The social work values of self-determination, truth telling, and peace, and principles of antioppression are central to this healing format. When oppressed peoples tell their stories, 'not primarily to entertain but to make a point – to demonstrate, describe, explain, or justify something to others', they move from a position of oppression, a state in which they were silenced, to a public expression of injustice (Young, 2002: p. 72).

Conclusion

This article has moved from a review of biological, psychological, and sociological theories about the nature of oppression to a theoretical/social action framework – the antioppressive model – which directly addresses the causes and consequences of oppression in society, and which has a major following among social workers and social work academics internationally. Insights from antioppressive perspectives can help social workers better understand the sources of injustice and oppression and productive ways of confronting them.

Optimal Control Theory

Ngo Van Long, McGill University, Montreal, QC, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article explains the basic structure of an optimal control problem, and shows how the optimal control theory can be usefully applied to the analysis of dynamic problems in behavioral sciences. Examples of applications in economics, finance, and management science are provided. Extensions to stochastic control theory and differential games are explained. The article concludes with notes on future directions for research.

The optimal control theory is a mathematical theory that deals with optimizing an objective function in a dynamic environment. In this theory, there are two basic types of variables: state variables and control variables. The state variables describe the current state of the system, for example, a state variable may represent the stock of equipment present in the economy, the size of a forest, the amount of carbon dioxide in the atmosphere, or a biomass of a certain fish species in a given lake. The control variables are what the decision makers can directly control, such as the rate of investment or the harvesting efforts. A system of differential equations, often called the transition equations, describes how the rate of change of each state variable at a given point of time depends on the state variables and the control variables, and possibly on time itself. Given the initial values of the state variables (often called the initial stocks), the decision maker chooses the time path of the control variables. This choice determines the rates of change of the state variables, and hence their future values. The objective of the decision maker is to maximize some performance index, such as the value of the stream of discounted profits, or some index of the level of well-being of a community, which may depend on current and future values of the control variables and the state variables. Solving an optimal control problem means determining the time paths of all the control variables so as to maximize the objective function.

It turns out that in solving an optimal control problem, it is useful to add a new set of variables, called costate variables; for each state variable, one assigns a corresponding costate variable. In economics, the costate variables are often called shadow prices, because each costate variable is an indicator of the worth of the associated state variable to the decision maker. With this additional set of variables, one can formulate an elegant set of necessary conditions, called the maximum principle, which is extremely useful in constructing the solution for the optimal control problem, and which, as a bonus, provides deep insight into the nature of the solution.

The Maximum Principle

We now define a simple optimal control problem and state the maximum principle for it. Let t denote time. Let $s(t) = (s_1(t), s_2(t), \ldots, s_n(t))$ the vector of n state variables, and $c(t) = (c_1(t), c_2(t), \ldots, c_m(t))$ be the vector of m control variables (m can be greater than, equal to, or less than n). The transition equations are given by

$$ds_i(t)/dt = f_i(s(t), c(t), t) \quad i = 1, 2, \ldots, n$$

The initial values of the state variables are $s_i(0) = s_{i0}$, $i = 1, 2, \ldots, n$. The terminal time T is fixed in this simple problem. The decision maker must find the time path of $c(t)$ to maximize the sum of (1) the value of the integral of the flow of benefit, with the benefit at time t being denoted by $u(s(t), c(t), t)$, and (2) the decision maker's valuation of the terminal stock, denoted by $\phi(s_T, T)$.

$$\int_0^T u(s(t), c(t), t)dt + \phi(s_T, T)$$

(The functions $u(.)$, $\phi(.)$ and $f_i(.)$ are exogenously specified.) At each time t, the values that $c(t)$ can take on are restricted to lie in a certain set A.

For each state variable s_i, one introduces a corresponding costate variable π_i. Let $\pi(t) = (\pi_1(t), \pi_2(t), \ldots, \pi_n(t))$. The costate variables must satisfy certain conditions, as set out below, and their optimal values must be determined as part of the solution of the problem. A key step in solving an optimal control problem is the construction of a function called the Hamiltonian, denoted as $H(s(t), c(t), \pi(t), t)$, and defined as

$$H(s(t), c(t), \pi(t), t) = u(s(t), c(t), t) + \sum_{i=1}^{n} \pi_i(t) f_i(s(t), c(t), t)$$

The maximum principle states that an optimal solution to the above problem is a triplet $(s(t), c(t), \pi(t))$ that satisfies the following conditions.

1. $c(t)$ maximizes $H(s(t), c(t), \pi(t), t)$ for given $s(t)$, $c(t)$, and t, over the set A. (This is a very attractive property, because the Hamiltonian can be interpreted as the sum of the current benefit and an indicator of future benefits arising from current actions, as reflected in the value of the rates of changes of the state variables that are influenced by the control variables.)
2. The costate variables and the state variables are related by the following differential equations

$$d\pi_i(t)/dt = -\partial H/\partial s_i(t), \quad i = 1, 2, \ldots, n$$

$$ds_i(t)/dt = \partial H/\partial \pi_i(t), \quad i = 1, 2, \ldots, n$$

Note that the first differential equation has the following appealing interpretation. The costate variable $\pi_i(t)$ being the shadow price of the state variable $s_i(t)$, the left-hand side of that equation may be thought of as the capital gain (the increase in the value of that asset). The optimal level of asset holding must be such that the sum of (1) the marginal contribution of that asset, $\partial H/\partial s_i(t)$, and (2) the capital gain term is equal to zero, (3) $2n$ boundary conditions must be met, namely, $s_i(0) = s_{i0}$, $i = 1,2,\ldots,n$ and

$$\pi_i(T) = \partial\phi/\partial s_i(T), \quad i = 1,2,\ldots,n$$

These last n conditions given are also called the transversality conditions. They say that at the terminal time T there must be an equality between $\pi_i(T)$ (the 'internal worth' of the stock i) and its 'external worth' at the margin (recall that the function $\phi(.)$ is externally specified).

The optimal time path of the control variables can be represented in the open-loop form, i.e., each $c_i(t)$ is expressed as a function of time, having as parameters the initial conditions $s_i(0)$, $i = 1,2,\ldots,n$; closed-loop form; or feedback form, i.e., an optimal rule that determines $c(t)$ using only the knowledge of the concurrent values of the state variables, and of t.

There are more complicated optimal control problems, which may involve several initial or terminal constraints on the state variables, the optimal choice of the terminal time T (no longer fixed) or of the initial time (e.g., at what time a mining firm should abandon a mine, a researcher should drop a research project, or a city should start building an airport). These problems give rise to a complex set of transversality conditions; see Léonard and Long (1992) for a useful tabulation.

Connections with the Calculus of Variations and Dynamic Programming

The optimal control theory has its origin in the calculus of variations, which concerns essentially the same types of optimization problems over time. However, with the maximum principle, developed by Pontryagin and his associates (see Pontryagin et al., 1962), the class of problems that the optimal control theory can deal with is much more general than the class solvable by the calculus of variations.

The optimal control theory is formulated in continuous time, although there is also a discrete time version of the maximum principle; see Léonard and Long (1992). In discrete time, the most commonly used optimization technique is dynamic programming, developed by Bellman (1957), using a recursive method based on the principle of optimality. Bellman's principle of optimality can also be formulated in continuous time, leading to the Hamilton–Jacobi–Bellman equation (or HJB equation for short), which is closely related to Pontryagin's maximum principle, and is often used to provide a heuristic proof of that principle (see Arrow and Kurz, 1970). Such a heuristic proof reveals that the shadow price (i.e., the costate variable) of a given state variable is in fact the derivative of the value function (obtained by solving the HJB equation) with respect to that state variable, thus justifying the name shadow price. This approach yields equations that are in agreement with (2) in the preceding section.

Applications of Optimal Control Theory to Economics, Finance, and Management Sciences

Economists initially used the optimal control theory primarily to address the problem of optimal capital accumulation and optimal management of natural resources and the environment (Arrow and Kurz, 1970; Pitchford and Turnovsky, 1977; Kemp and Long, 1980). The optimal control theory has been used to study a variety of topics, such as macroeconomic impacts of fiscal policies (e.g., the effect of a temporary increase in government spending on private consumption and investment) and optimal consumption planning of an individual. (For example, Becker and Murphy (1988) addressed the question of rational addiction: if you know that your current level of consumption of a drug will determine your degree of addiction, which in turn will increase your future demand for it, how should you determine your time path of consumption of the drug, knowing the consequence of addiction?) Recently, the optimal control theory has been used to explore conditions under which a Green Paradox might occur: given that oil firms optimize their time path of production, would a rising time path of carbon tax (which is meant to discourage the use of fossil fuels) make them extract their resource stocks faster, bringing global warming damages closer to the present? (see Sinn, 2008.)

In management sciences, optimal control has been the management of problems such as the optimal holding of inventories, the optimal time path of advertising (e.g., under what conditions would it be optimal to vary the intensity of advertising over the product cycle), the optimal maintenance and sale age of a machine subject to failure, and so on. In finance, theories of optimal portfolio adjustment over time, and theories of pricing of financial options, have been developed using optimal control methods, in a stochastic setting (see Malliaris and Brock, 1982).

It is important to note that while the variable t often stands for time, and the objective function is often an integral over a time interval, it is not necessary to restrict the theory to that interpretation. In fact, in some important applications of the optimal control theory to economics, t has been interpreted as an index of the type of an individual in a model where there is a continuum of types.

Extensions of Optimal Control Theory

There are two important extensions of the optimal control theory. The first extension consists of allowing for uncertainty in the transition equations, leading to the development of stochastic control theory. The second extension is to allow for strategic interactions among decision makers who pursue different objectives, or who have diametrically different interests. The body of literature that deals with this extension is called the theory of differential games.

Stochastic Optimal Control Theory

A typical transition equation in the stochastic optimal control theory is

$$ds(t) = f(s(t), c(t)) + g(s(t), c(t))$$

where dz represents an increment in a stochastic process z called the Wiener process. In this equation, $f(s(t),c(t))$ is the expected rate of change in the state variable s, the term dz represents a random disturbance in the external environment, and $g(s(t),c(t))$ indicates that the effect of the disturbance on the evolution of the state variable may depend on the values taken by the control variable and the state variable.

In some contexts, it is more appropriate to consider random disturbances that occur only rarely, but that may have great impacts when they occur, for example, an earthquake, a currency crisis, or a discovery of an entirely new production technique. To deal with such discrete events, the Poisson process (also called jump process) is used instead of the Wiener process, which is suitable for continuous random variations.

In finding a solution of a stochastic control problem, one makes use of a stochastic version of the HJB equation. Sometimes it is possible to provide an explicit solution in the feedback form. For example, some adjustment rules for portfolios of financial assets can be derived. Another interesting application of the stochastic optimal control theory is the problem of determining the optimal time to switch from one regime to another. This is often referred to as the optimal stopping problem. One asks, for example, when one should exercise a call option (stop waiting for a further increase in price), or when to start setting up a factory in a foreign country (stop waiting for a further favorable movement in the exchange rate).

Differential Games

A differential game is a game involving N players, each solving an optimal control problem, knowing that the other players are also solving their own optimal control problems, and that these problems are related because the controls chosen by each player have an impact on the evolution of the state variables, and possibly on the benefit functions u_i. An example of a differential game is the transboundary fishery problem faced by two adjacent coastal nations. Each nation knows that the other nation's harvesting strategy will have an impact on the growth rate of the fish stock. If the two nations do not cooperate, they are said to be playing a noncooperative differential game. In trying to predict the outcome of such games, theorists have formulated various concepts of equilibrium. A Nash equilibrium of a differential game is a pair of strategies, one for each player, such that each player's strategy is the best course of action (i.e., it solves the player's optimal control problem), given the strategy of the other players.

The nature of the solution depends on the set of strategies available to the players. If one assumes that, given the initial conditions, the players can only choose control variables as functions of time (and not as a function of the concurrent values of the state variables), then the strategies are called open-loop strategies, and the resulting Nash equilibrium is an open-loop Nash equilibrium. On the other hand, if players can observe values of the state variables and choose closed-loop strategies (i.e., strategy that specify the values to be taken by their control variables at any time as functions of the concurrent values of the state variables, and possibly of time as well) then the resulting equilibrium is a closed-loop Nash equilibrium. A refinement of the closed-loop Nash equilibrium requires that at any point of time, and given any situation the system may reach, the strategy chosen by each player must remain optimal for that player, given that other players also stick to their chosen strategies. This property is called subgame perfectness. A closed-loop Nash equilibrium that satisfies the subgame perfectness property is called a Markov-perfect Nash equilibrium.

Both deterministic and stochastic differential games have been applied to problems in economics and management science. Examples include games of transboundary fishery, advertising games, innovation games, global warming games, and so on (see Dockner et al., 2000 and Long, 2010).

Conclusions and Future Directions

The optimal control theory has become a standard tool in economics and management science. It has facilitated the solution of many dynamic economic models, and helped to provide a great deal of insight into rational behavior and interaction in a temporal context. Several unsolved problems are currently attracting research interests. Among these are (1) finding Markov-perfect equilibrium in more general games (such as games with leaders and followers) and (2) allowing coalitions of players to be formed or dissolved as the games proceed.

Optimal Experimental Design

Anthony C Atkinson, Department of Statistics, London School of Economics, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The methods of optimal experimental design allow cogent comparisons of designs and provide algorithms for the construction of designs in nonstandard cases. This article covers optimal design for simple regression and then develops the general theory. A sequence of designs for specific models of increasing complexity include the 2^m factorials and their fractions and generalized linear models, particularly the logistic linear model for binary data. Results on parameter uncertainty are applied to designs for conjoint choice experiments and nonlinear regression. Reference is made to several recent books and to sources of numerical algorithms.

Introduction

Theoretical results from optimal experimental design allow the comparison of proposed designs and the selection of the design that is most efficient for the specific purpose of the experiment. For example, power of important tests of hypotheses may be maximized. Methods derived from the theory provide algorithms for the construction of designs in nonstandard cases, such as those when certain treatment combinations are impossible or when responses are nonnormal.

Many experiments in behavioral science have a simple treatment structure. Study 3 of Correll et al. (2007) on the decision to shoot by police officers uses a four factor design with all factors at two levels, that is, a full 2^4 factorial design. In contrast, the choice experiments described in Section Conjoint Choice Designs of this article have a complicated structure, the selection of items to be compared depending on prior beliefs about parameter values. Optimal design algorithms are essential for the efficient design of such experiments.

Although the factorial design of Correll et al. (2007) has a simple structure, Sherman and Strang (2004) stress the close relationship between experimental designs in behavioral science and those in agriculture and medicine, where there may be important heterogeneity between experimental subjects. The data analysis of Correll et al. (2007) is for the 58 participants who completed the full set of factorial tasks, for whom some information is given on gender and ethnicity. However, there is no analysis of the heterogeneity in responses using these covariates, perhaps because of serious imbalance – only one participant was black. Atkinson and Biswas (2014: Chapter6) describe optimal design methods for balancing treatment allocation over covariates in clinical trials.

This article starts in Section Simple Regression with optimal design for simple regression. The next three sections develop the general theory of optimal design, before attention turns to designs for specific models of increasing complexity. Section 2^m Factorial Designs and Fractions covers the 2^m factorials and their fractions. Generalized linear models are in Section Generalized Linear Models with a discussion of the effects of parameter uncertainty on designs for nonlinear models in Section Optimal Design and Parameter Uncertainty. Section Locally Optimal Designs for Logistic Regression in One Variable illustrates these topics with designs for the linear logistic model. Designs for the related conjoint choice experiments are in Section Conjoint Choice Designs with designs for nonlinear regression models in Section Nonlinear Regression Models. The article concludes with a brief mention of the algorithms for design construction that are such an important consequence of the theory of optimal design.

Simple Regression

Many optimal designs minimize the variances of estimated parameters, or the variances of functions of the parameters, such as predictions. We therefore need to specify a model. The simplest interesting case is linear regression in one variable, which serves to introduce some important ideas. Section Locally Optimal Designs for Logistic Regression in One Variable describes designs for models with binary responses.

There is a single response y, the expected value of which depends linearly on the value of the variable x through the relationship $E(y) = \beta_0 + \beta_1 x$. The design problem is to choose N values of x at which measurements are to be taken. Although there are N observations, the number of distinct values of x used in the experiment, n, may be much less than N. These n values of x must lie in the experimental region χ, determined by experimental constraints. For a single variable we can scale the values of x such that $-1 \le x \le 1$ where ± 1 correspond to the minimum and maximum values of the variable.

When the variance of the observations is constant, that is $\mathrm{var}(y) = \sigma^2$, least squares is the appropriate method of parameter estimation. The least squares estimators of the parameters are $\widehat{\beta}_0$ and $\widehat{\beta}_1$ with

$$\mathrm{var}\left(\widehat{\beta}_1\right) = \sigma^2 \Big/ \sum (x_i - \bar{x})^2 \qquad [1]$$

where the sample average $\bar{x} = \sum x_i / N$. Here and in eqn [1], the summations are over all N values x_i. From eqn [1], the variance of $\widehat{\beta}_1$ is minimized when $\sum (x_i - \bar{x})^2$ is maximized. For a fixed number of trials N this occurs when all trials are at $+1$ or -1. If N is even, exactly half the trials will be at $x = +1$ and the other half at $x = -1$. This design has $\bar{x} = 0$, so that $\mathrm{var}(\widehat{\beta}_0) = \sigma^2/N$, which does not depend any further on the design. This design is therefore optimal for both parameters.

This design exhibits several features of optimal designs. The number of support points of the design n, here two, may be

appreciably less than the number of trials N. The fine structure of the design depends on the value of N, here whether it is even or odd, in which case one more trial is put at one end of the design region than at the other; it does not matter which. A third feature is that the design covers the whole of the design region, using the most extreme values of x available. In any application of the design, the order in which the two treatments $x = -1$ and $x = 1$ are applied should be randomized to avoid any confounding with omitted variables.

The optimal design found here for parameter estimation also has a minimax property for prediction: it minimizes the maximum variance of the prediction $\widehat{y}(x)$ over χ.

Optimal designs are tailored to the model that is assumed; particularly when there is one factor, the designs often have the same number of design points as there are parameters. An example is the design at two points for the two-parameter regression model. An objection to such a design is that it does not provide for checking the model, for which trials at three or more values of x are needed. This suggests that the design should also be efficient in case the relationship is a second-order model

$$E(y) = \beta_0 + \beta_1 x + \beta_2 x^2 \qquad [2]$$

It is always possible that an even higher-order model is required, but third- or higher-order models are rarely needed. If such models seem to be required, data transformations, such as the power transformations analyzed by Box and Cox (1964), are often called for.

Design for the three-parameter second-order model, eqn [2], introduces further aspects of the dependence of the optimal design on the precise purpose of experimentation. Unlike the two-point design for the first-order model, there is now no overall optimal design for all parameters. Testing whether the first-order model is adequate is equivalent to testing whether $\beta_2 = 0$. The variance of $\widehat{\beta}_2$ is minimized by a design that puts half the trials at $x = 0$ and divides the remaining half between $x = -1$ and $x = 1$. But the design that provides the best estimates of all three parameters, in the sense of D-optimality described in the next section, puts one-third of the trials at each of these three points. In a satisfactory manner, the optimal design depends on the precise purpose of the experiment.

Criteria of Optimality

This section mainly describes the criterion of D-optimality, which provides designs minimizing the generalized variance of the estimated parameters.

We consider a general experiment in which there are m factors and write the linear model as

$$E(y) = F\beta \qquad [3]$$

Here y is the $N \times 1$ vector of responses, β is a vector of p unknown parameters, and F is the $N \times p$ *extended* design matrix. The ith row of F is $f^T(x_i)$, a known function of the m explanatory variables. For the quadratic model eqn [2], for which $m = 1$ and $p = 3$, $f^T(x_i) = \begin{pmatrix} 1 & x_i & x_i^2 \end{pmatrix}$. The design is determined by the experimental values of x. The *extended* design matrix reflects not only the design but in addition the model to be fitted.

For the moment we continue to assume that the observational errors are independent with constant variance, σ^2. The least squares estimator of the parameters can be written as

$$\widehat{\beta} = \left(F^T F\right)^{-1} F^T y \qquad [4]$$

where the $p \times p$ matrix $F^T F$ is the information matrix for β. The larger $F^T F$, the greater is the information in the experiment.

With σ^2 constant, the covariance matrix of the least squares estimator is

$$\operatorname{var} \widehat{\beta} = \sigma^2 \left(F^T F\right)^{-1} \qquad [5]$$

When interest is in the comparison of experimental designs, the value of σ^2 is not relevant, since it is the same for all proposed designs for a particular experiment.

The volume of the confidence ellipsoid for all p elements of β is inversely proportional to the square root of the determinant $\left|F^T F\right|$. Designs which maximize $\left|F^T F\right|$ minimize the generalized variance of $\widehat{\beta}$ are called D-optimal (for Determinant).

Interest in the fitted model may be not only in the parameters, but also in the quality of the predictions. The predicted value at x of the fitted response for the p-parameter model eqn [3] is

$$\widehat{y}(x) = \widehat{\beta}^T f(x) \qquad [6]$$

with variance

$$\operatorname{var} \widehat{y}(x) = \sigma^2 f^T(x) \left(F^T F\right)^{-1} f(x) \qquad [7]$$

Designs which minimize the maximum over χ of $\operatorname{var} \widehat{y}(x)$ are called G-optimal. As the theorem of Section The General Equivalence Theorem and Design Efficiency indicates, as N increases, D-optimality and G-optimality give increasingly similar designs.

An alternative to this minimax approach to $\operatorname{var} \widehat{y}(x)$ is to find designs that minimize the average value of the variance over χ. Such designs are variously called I-optimal or V-optimal from Integrated Variance. Another criterion of importance in applications, particularly for nonlinear models, is that of c-optimality in which the variance of the linear combination $c^T \widehat{\beta}$ is minimized, where c is a $p \times 1$ vector of constants. When c is a vector of zeroes and ones, the criterion selects a subset of parameters and reduces to **D_S-optimality**. We do not exhibit such designs in this article, but focus on D- and G-optimality. Details of these and other design criteria are in Chapter 10 of Atkinson et al. (2007). Goos and Jones (2011: Section 4.3.5) stress the advantages of I-optimality.

Exact and Continuous Designs

Instead of finding *exact* optimal designs for specific values of N, there are mathematical and computational advantages in finding the limiting *continuous* design independent of N. Such designs can both easily be checked for optimality and readily be approximated to provide good exact designs for many N.

The theory was introduced in Kiefer (1959) and developed in a series of further papers. Kiefer's work on optimal design is collected in Brown et al. (1985). A basic idea is to write designs as probability measures on the n support points of the design

$$\xi = \begin{Bmatrix} x_1 & x_2 \ldots x_n \\ w_1 & w_2 \ldots w_n \end{Bmatrix} \quad [8]$$

where the weights $w_i > 0$ and $\sum w_i = 1$. The measure ξ therefore specifies the experimental conditions and the proportion of experimental effort at each condition.

The information matrix can be written in terms of this measure as

$$M(\xi) = \sum w_i f(x_i) f^T(x_i) \quad [9]$$

The variance of the predicted response can be written in the standardized form

$$\mathrm{d}(x, \xi) = f^T(x) M^{-1}(\xi) f(x) \quad [10]$$

At the end of Section Simple Regression it was stated that the D-optimal design for the quadratic model in one variable with $\chi = [-1, 1]$ put weights one-third at each of the three levels of x: -1,0, and 1. For any N that is a multiple of three, the exact optimal design puts $N/3$ trials at each of these sets of experimental conditions. For other values of N a good design is to distribute the trials as evenly as possible over these three points.

The General Equivalence Theorem and Design Efficiency

D-optimal continuous designs maximize $|M(\xi)|$. Kiefer and Wolfowitz (1959) provide an equivalence theorem, relating D- and G-optimal designs, that provides a method of checking the D-optimality of a continuous design.

If ξ^* is a D-optimal design measure, then ξ^* also minimizes the maximum over χ of the standardized variance of prediction $d(x, \xi)$ given by eqn [10]; that is ξ^* is also G-optimal. If we write this maximum as

$$\overline{d}(\xi) = \max_{x \in \chi} d(x, \xi) \quad [11]$$

then $\overline{d}(\xi^*) = p$, the number of parameters of the linear model. For any nonoptimal design ξ the maximum over χ of $d(x, \xi)$ is greater than p, which provides a method for checking for D-optimality.

The theorem holds for continuous optimal designs and, of course, for exact designs with replications that are an integer multiple of the weights of the continuous designs. But, for example, the exact D-optimal design for the quadratic model when N is not a multiple of three will not satisfy the theorem.

To compare a continuous design ξ with the optimal design ξ^* we define the D-efficiency as

$$D_{\text{eff}} = \left\{ \frac{|M(\xi)|}{|M(\xi^*)|} \right\}^{1/p} \quad [12]$$

The comparison of information matrices for designs that are measures removes the effect of the number of observations. Taking the pth root of the ratio of the determinants in eqn [12] results in an efficiency measure which has the dimensions of variance, irrespective of the dimension of the model. Since the variance of estimated regression coefficients is inversely proportional to the number of observations, two replicates of a design measure for which $D_{\text{eff}} = 50\%$ would be as efficient as one replicate of the optimal measure.

Quadratic Model in One Variable

The claim that the final design of Section Simple Regression with weights 1/3 is D-optimal for the quadratic model when $\chi = [-1, 1]$ can be checked using the General Equivalence Theorem through calculation of the variance of the predicted response.

For this design $\mathrm{d}(x, \xi^*)$ is the quartic given by

$$\mathrm{d}(x, \xi^*) = 3 - 9x^2/2 + 9x^4/2 \quad [13]$$

which has a maximum over χ of 3 at $x = -1$,0, or 1, the three design points. Further, this maximum value is equal to the number of parameters p. The plot in **Figure 1** exhibits the optimality of the design since the values of three at the design points are indeed the optima over χ.

Equivalence theorems for other criteria are given in Chapter 10 of Atkinson et al. (2007).

Figure 1 Quadratic model in one variable; $d(x, \xi^*)$ over χ for the design putting equal weights at $x = -1$, 0, and 1. Since the maximum value is three, which is the number of parameters in the model, the design is D-optimal.

2^m Factorial Designs and Fractions

The first-order model in m factors with main effects and all possible interactions may be written as

$$E(\gamma) = \beta_0 + \sum_{i=1}^{m} \beta_i x_i + \sum_{i=1}^{m-1} \sum_{j=1+1}^{m} \beta_{ij} x_i x_j + \cdots + \beta_{ijk\ldots} x_i x_j x_k \cdots \quad [14]$$

When χ is cuboidal, the D-optimal continuous design is the equireplicated 2^m factorial, which has $n = 2^m$ points of support at all combinations of values of ± 1 for each factor. If the full model eqn [14] is fitted $p = N$ and $M(\xi^*)$ is the identity matrix, then $\mathrm{d}(x, \xi^*) = p$ at the design points and the equivalence theorem for continuous D-optimality is satisfied. Because of the orthogonality of the design, reflected in the diagonal nature of $M(\xi^*)$, the same design is optimal if terms are omitted from eqn [14] or if the design is projected by the omission of one or more factors. Provided all the terms in the model can be estimated, the regular fractions of the design, that is the series of 2^{m-f} fractional factorials, are also the continuous D-optimal designs.

The 2^{m-f} fractional factorials are often used when it is known that some interactions are not important and the full factorial design will lead to unnecessarily precise estimation of the parameters, with a consequent waste of resources. However, these orthogonal fractions are restricted to values of N that are powers of 2. Goos and Jones (2011: Section 8.2.2) demonstrate the use of algorithmic methods for the construction of optimal designs that find fractional factorials for a specified value of N. Although the designs are not quite orthogonal, highly efficient parameter estimates are obtained.

Generalized Linear Models

The Family of Models

The family of generalized linear models (McCullagh and Nelder, 1989) extends normal theory regression to several useful distributions, including the gamma, Poisson, and binomial. The models have three components:

- A distribution for the univariate response γ with mean μ.
- A linear predictor, $\eta = \theta^T f(x)$. As for regression, $f(x)$ is a vector of p known functions of the explanatory variables.
- A link function, $g(\mu) = \eta$, relating x to the mean μ.

The distribution of γ determines the relationship between the mean and the variance of the observations. The information matrix for a single observation at x is

$$M(x;\theta) = u(x) f(x) f^T(x) \quad [15]$$

with the weights $u(x)$ for individual observations depending on both the distribution of γ and the link function. Since eqn [15] is the information matrix for weighted least squares, there are important relationships between optimal designs for regression models and those for other generalized linear models.

Binomial Data

In models for binomial data with R successes in n observations, the response γ is defined to be R/n. The link function should be such that, however the values of x and θ vary, the mean μ satisfies the physically meaningful constraint $0 \le \mu \le 1$. The most commonly used link function is the logistic link in which

$$\eta = \log\{\mu/(1-\mu)\} \quad [16]$$

In this model the log odds is therefore equal to the linear predictor. The weight $u(x) = \mu(1-\mu)$. The weights for other links are more complicated.

Poisson Data

For Poisson data we require that $\mu > 0$. The log link, $\log \mu = \eta$, is standard for the analysis of Poisson data in areas such as medicine, social science, and economics; see, for example, Agresti (2002: Chapter 9). This link leads to models with $\mu = \exp \eta$, which satisfy the constraint on values of μ, and weights $u(x) = \mu$.

Gamma Data

The gamma family is one in which the correct link is often in doubt. The physical requirement is again that $\mu > 0$. A useful, flexible family of links that obeys this constraint is the Box and Cox family. (See Box and Cox, 1964 for the use of this function in the transformation of data.) For the special case of the log link, the weights $u(x)$ equal one. Therefore optimal designs for gamma models with this link are identical to optimal designs for regression models with the same linear predictors.

Optimal Design and Parameter Uncertainty

The optimal designs for regression in the earlier sections of this article maximized a function of the information matrix, $M(\xi)$, which did not depend on the values of the parameters of the model. However, for generalized linear models, the information matrix depends on θ through the weight function $u(x)$. We accordingly write the information matrix as $M(\xi;\theta)$ and consider maximization of some function, $\Psi\{M(\xi;\theta)\}$. The numerical values of θ required for this optimization can be specified in several ways.

Locally Optimal Designs

The optimal design is found for θ_0, a point prior estimate of θ, that is we maximize $\Psi\{M(\xi;\theta_0)\}$. In the conjoint choice designs of Section Conjoint Choice Designs these values serve to indicate the signs of effects, the designs being relatively insensitive to the precise values of θ_0.

Bayesian Designs

Let the prior distribution of θ be $p(\theta)$. Bayesian designs are found to maximize

$$\Psi\{M(\xi)\} = E_\theta \Psi\{M(\xi;\theta)\} = \int \Psi\{M(\xi;\theta)\} p(\theta) \mathrm{d}\theta \quad [17]$$

The ease of calculation depends on the form of the prior $p(\theta)$ and of $\Psi(.)$ as well as, often crucially, on the region of integration. The easiest case is when θ has a multivariate

normal distribution over $\Re^p$, although numerical approximation is still needed. For less amenable cases, a standard solution is to sample from the prior distribution and to use an average objective function. An example for a nonlinear model is in Section 18.5 of Atkinson et al. (2007).

Designs maximizing expectations such as eqn [17] ignore the additional effect of the prior information about θ on the information matrix and make no assumption of a Bayesian analysis. The designs are accordingly sometimes called pseudo-Bayesian. A discussion of Bayesian experimental design is given by Chaloner and Verdinelli (1995).

Sequential Designs

Where it is possible, sequential experimentation can provide an efficient strategy in the absence of knowledge of plausible parameter values. A locally optimal, or other initial, design is followed by alternating phases of parameter reestimation and locally optimal design based on the revised parameter estimates. The procedure stops when sufficient accuracy is obtained or the experimental resources are exhausted. An early example, for nonlinear regression, is Box and Hunter (1965), extended by Atkinson et al. (2007: Section 17.7). Dror and Steinberg (2008) developed a Bayesian sequential design methodology for generalized linear models.

Minimax and Maximin Designs

This approach replaces dependence of designs on the unknown value of θ by finding the best design for the worst case when the parameter θ belongs to a set Θ. A design, ξ^* is found for which

$$\Psi\{M(\xi^*)\} = \max_{\xi} \min_{\theta\in\Theta} \Psi\{M(\xi;\theta)\} \qquad [18]$$

A potential objection to these designs is that the minimax or maximin design is often close to a combination of locally optimal designs for values of θ at the edges of the parameter space. If a prior distribution is available, such points may have a very low probability; their importance in the design criterion may therefore be overemphasized by the minimax criterion. Providing adequate performance in these unlikely worst case scenarios may greatly affect overall design performance. These designs can also be hard to find. Numerical procedures are described in detail by Pronzato and Pázman (2013: Section 9.3). Minimax designs for generalized linear models have been found by Sitter (1992) and by King and Wong (2000).

Small Effects

If the effects of the factors are slight, the mean, μ_i of each observation will be similar, and so will the corresponding model weights, $u(x_i)$. The information matrix will then, apart from a scaling factor, be close to the unweighted information matrix, $F^{\mathrm{T}}F$ and the optimal designs for the weighted and unweighted matrices will be close. Optimal designs for generalized linear models with small effects will therefore be close to optimal designs for regression models with the same linear predictor (Cox, 1988).

Locally Optimal Designs for Logistic Regression in One Variable

With a single explanatory variable and the logistic link

$$\log\{\mu/(1-\mu)\} = \eta = \theta_0 + \theta_1 x \qquad [19]$$

it is clear that observations at values of x for which the responses are virtually all 0 or 1 will be uninformative about the values of the parameters. This intuitive result indeed follows from the weight $u(x) = \mu(1-\mu)$.

We start by finding the locally D-optimal design for the *canonical* case of $\theta = (0,1)^T$. With a response symmetrical about zero, the design can also be assumed symmetrical about zero. It is thus simple to find the D-optimal design as

$$\xi^* = \left\{ \begin{matrix} -1.5434 & 1.5434 \\ 0.5 & 0.5 \end{matrix} \right\} \qquad [20]$$

which puts equal weights at two points symmetrical about $x = 0$, provided χ is sufficiently large. At these support points, $\mu = 0.176$ and $1 - 0.176 = 0.824$.

Although designs for other values of the parameters can likewise be found numerically, design problems for a single x can often be solved in such a canonical form, yielding a structure for the designs independent of the particular parameter values.

For the upper design point in eqn [20] the linear predictor, $\eta = 0 + 1 \times x$ has the value 1.5434, which is the value needed for the optimal design whatever the parameterization. If we solve eqn [19] for the η giving this value, the upper support point of the design is given by $x^* = (1.5434 - \theta_0)/\theta_1$.

For linear regression the D-optimal design puts half of the design weight at the two extreme values of χ, whereas, for logistic regression, the design does not span χ, provided the region is sufficiently large. Note that as $\theta_1 \to 0$, the value of x^* increases without limit. This is an example of the result of Cox (1988) mentioned above. In practice, the design region will not be unlimited and, depending on θ, the optimal design may put weight on one boundary point and an internal point, or on the two boundary points of χ.

Ford et al. (1992) provide similar results on the structure of designs for other single-variable generalized linear models. Optimal designs for models with more than one explanatory variable usually have to be found numerically. The optimality of continuous designs can again be checked using an equivalence theorem. For D-optimality, eqn [10] is replaced by the weighted form $\mathrm{d}(x,\xi) = u(x)f^T(x)M^{-1}(\xi)f(x)$.

Chapter 22 of Atkinson et al. (2007) provides examples of the numerical calculation of locally optimal designs for logistic and gamma models with two explanatory variables. Atkinson and Woods (to appear) collect results on optimal designs for models with multifactor first-order linear predictors. They also calculate Bayesian and other designs when there is uncertainty about the values of the parameters, and discuss designs for dependent data arising from random effects in the model.

Conjoint Choice Designs

Conjoint choice experiments are frequently performed in marketing and other fields of behavioral research in order to

establish individual preferences between items. The factors are typically discrete and at a few levels. As an example, factors in the choice between laptop computers might include discretized values of weight, RAM, screen size, computational speed, and price. The design region, χ consists of all feasible combinations of the factors (and so may not form a full factorial array, since such extremes as cheap fast computers with large screens are not a practical reality). A single observation comes from comparing the desirability of J items formed by choosing J rows from χ to give a choice set, s. The utility attached to x_j, the jth row of χ, is customarily modeled as $\propto x_j^{\mathrm{T}}\beta$ plus an error term. Since only comparisons between items are meaningful, the first-order model excludes a constant.

The response to the experiment might be a scoring or ranking of the J items. However, the literature summarized by Kessels et al. (2006) indicates that results closest to purchasing behavior are obtained by asking the subject to choose one of the J items. Then the multinomial logit probability model that profile j in choice set s is chosen as

$$p_{js} = \exp\left(x_{js}^{\mathrm{T}}\beta\right) \Big/ \left\{\sum_{\iota=1}^{J} \exp\left(x_{\iota s}^{\mathrm{T}}\beta\right)\right\} \qquad [21]$$

The design matrix for choice set s is the $J \times p$ matrix, X_s, with rows $x_{\iota s}^{\mathrm{T}}$, $(\iota = 1, \ldots, J)$. In the simplest case, each subject performs evaluations of N choice sets. The information matrix for the exact design for a single subject is then

$$NM(\xi_N) = \sum_{s=1}^{N} X_s^{\mathrm{T}}\left(P_s - p_s p_s^{\mathrm{T}}\right)X_s \qquad [22]$$

where $p_s = (p_{1s}, \ldots, p_{Js})^T$, $P_s = \mathrm{diag}(p_{1s}, \ldots, p_{Js})$, and p_{js} is given by eqn [21]. The number N of choice sets seen by each subject is determined by how quickly subjects are expected to tire. The number of subjects is determined by N, the available resources, and the desired accuracy. The remaining optimal design problem is then to determine the N choice sets of size J that maximize the exact information matrix eqn [22]. Often J is taken as two.

Clearly, maximization of a function of eqn [22] is related to the optimal design problems for generalized linear models of Section Generalized Linear Models. In particular, the design depends on the unknown parameters, β through the probabilities p_{js} in eqn [21]. The problems caused by parameter uncertainty described in Section Optimal Design and Parameter Uncertainty, and the methods for their solution, therefore also apply to choice experiments.

The locally optimal design with all elements of $\beta = 0$ is called utility neutral, since there is no prior expression of any preference between elements of χ. The optimal designs are then related to the factorials and their fractions of Section 2^m Factorial Designs and Fractions. Kuhfeld and Tobias (2005) describe algorithms for the construction of such designs. However, many of the sets selected by utility neutral designs may result in noninformative choices. For example, it is clear in comparing computers that higher speed and lower weight are both desirable. Accordingly, Kessels et al. (2006) provide algorithms for D-optimal and other designs for these models.

Two further points are important. The model of utility used in eqn [21] assumes a fixed effect, that is, that all subjects have the same value for the parameter β. However, parameters are likely to vary between subjects, leading to random effects models (Yu et al., 2009). Further, the experiments are sequential, so that it should be possible to learn about a subject's parameter value in real time. However, at present, the algorithms are not fast enough to allow updating without severely delaying the subject's flow of answers.

Nonlinear Regression Models

The dependence of designs for generalized linear models on the parameters θ entered only through the weight function, $u(x)$. In nonlinear models, such as those derived from chemical kinetics, the response function may depend nonlinearly on all the parameters in a more complicated way.

For example, in the compartmental model presented by Box and Lucas (1959) the mean of the regression model is

$$E(Y) = \eta(t, \theta) = \theta_3\{\exp(-\theta_2 t) - \exp(-\theta_1 t)\} \quad (t \geq 0) \qquad [23]$$

with all three parameters positive and $\theta_1 > \theta_2$. The exponential structure of such models reflects an underlying scheme of first-order chemical reactions.

Locally optimal designs are found by Taylor series expansion. Let θ be of dimension $p \times 1$, with θ_0 the vector of p prior values of θ. Then the vector of partial derivatives of the model, often called parameter sensitivities, is

$$f^T(t, \theta_0) = \left\{\frac{\partial\eta(t,\theta)}{\partial\theta_1}\frac{\partial\eta(t,\theta)}{\partial\theta_2}\cdots\frac{\partial\eta(t,\theta)}{\partial\theta_p}\right\}\Bigg|_{\theta=\theta_0}$$

which forms the terms of the p variable linearized multiple regression model. The vector of sensitivities for observation i is written, $f^T(t_i, \theta)$ and forms row i of the extended design matrix F for this linearized model; the information matrix is $F^{\mathrm{T}}F$. Note that θ_3 occurs linearly in eqn [23], so that optimal designs will not depend in the value of this parameter.

Chapter 17 of Atkinson et al. (2007) describes a variety of approaches to design for nonlinear models. Because of the dependence of the designs on unknown parameter values, the results of Section Optimal Design and Parameter Uncertainty are again pertinent.

Discussion and Literature

The principles and theory of optimal experimental design can yield insight into the form of efficient experiments. However, application of the methods to the more complicated, parameter-dependent, designs in Sections Generalized Linear Models; Optimal Design and Parameter Uncertainty; Locally Optimal Designs for Logistic Regression in One Variable; Conjoint Choice Designs and Nonlinear Regression Models may require powerful numerical algorithms.

Atkinson et al. (2007) relies on SAS software for the numerical calculation of designs. A general discussion of some algorithms for continuous designs harnessing the power of standard optimization methods is in Sections 9.4 and 9.5. Chapter 12 covers the rather different algorithms needed for the construction of exact D-optimal designs. The book of Goos

and Jones (2011) proceeds by numerical examples using JMP software to find exact designs and illustrate the methods of optimal design. The basic method is the coordinate-exchange algorithm introduced by Meyer and Nachtsheim (1995).

The first exposition of optimal design in its modern form is Kiefer (1959), although the subject goes back to Smith (1918). In addition to the books already cited in this article, recent books on optimal design include Fedorov and Leonov (2014), who provide a solid introduction to the theory of optimal design illustrated with pharmaceutical applications, particularly dose finding. Pronzato and Pázman (2013) present the theory of optimal design for nonlinear models. Berger and Wong (2009) are more concerned with applications.

Optimism and Pessimism

Charles S Carver, University of Miami, Coral Gables, FL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Optimism is the extent to which people hold favorable expectancies for their future. Higher optimism has been linked to higher engagement coping and lower avoidance coping. Optimism is also associated with taking proactive steps to protect health, whereas pessimism is associated with health-damaging behaviors. The energetic, task-focused approach that optimists take to goals also predicts benefits in the socioeconomic world. Optimism predicts more persistence in educational effort and higher later income. Optimists also appear to fare better than pessimists in relationships. Although optimism sometimes fails to convey an advantage, and occasionally may even convey a disadvantage, those instances are rare.

The concepts of optimism and pessimism are rooted in centuries of folk wisdom about core differences among people. In this case, the difference among people is in their expectations for the future. This difference has reverberations throughout people's lives and relationships with other people. Optimists, expecting to see the best, tend to find the best in whatever circumstances they confront. Pessimists, expecting trouble at every turn, tend to experience all of life as less than what it ought to be.

Contemporary research on optimism and pessimism also has its roots in people's expectations for the future (Carver and Scheier, 1998, 2014; Carver et al., 2010; Segerstrom, 2006). In taking that starting point, this body of research connects to more than a century of psychological theory. That is, the expectancy construct links research on optimism to a collection of theories of motivation and action that collectively are called expectancy-value theories (Eccles and Wigfield, 2002). This link, in turn, provides a clear rationale for examining the way in which the traits of optimism and pessimism are expressed in motivation, behavior, and feelings.

Expectancy-value models begin with the idea that behavior is aimed at attaining desired goals. These goals reflect the 'values' in the label expectancy value. Without a valued goal, there is no reason to act. The other element is expectancy: confidence or doubt about being able to attain the goal. If a person lacks confidence, again there will be no action. Only with sufficient confidence do people exert efforts and remain engaged in those efforts. These principles pertain to specific values and focused confidence, and they also apply to the more general traits of optimism and pessimism. In optimism and pessimism the 'confidence' involved is simply broader in scope.

These motivational principles provide the basis for many predictions about optimists and pessimists: When confronting a challenge, optimists should take a posture of confidence and persistence, even if progress is difficult or slow. Pessimists should be more doubtful and hesitant, quicker to give up their efforts. This divergence should be amplified under conditions of adversity. Optimists are likely to believe the adversity can be handled successfully; pessimists are likely to anticipate disaster. These differences in orientation can lead to differences in active efforts to take precautions, differences in persistence, differences in many decisions and actions that pertain to health and other risks, and differences in how people approach relationships.

People's overt behavioral responses to adversity are important, but overt behavior is not the only response that occurs when people confront adversity. People also experience emotions in such situations. Encountering difficulties results in a mixture of feelings and optimism influences the balance among the feelings. Again, predictions are easily derived from theory. Optimists expect to have good outcomes, even when things are difficult. This confidence should yield a more positive mix of feelings. Pessimists expect bad outcomes. This should be related to more intense negative feelings – anxiety, sadness, or despair.

Relations between optimism and distress have been examined in a wide range of contexts (Carver et al., 2010). The studies that have been done vary in complexity and what they are therefore able to show. Some of the work is cross-sectional, showing only that lower optimism relates to reports of more distress in some difficult situation. Those studies cannot show whether pessimistic people had more distress even prior to the adversity. Other studies assess people at multiple time points. These studies give a better picture of how distress shifts over time and circumstances and allow researchers to control for initial levels of distress.

A good deal of the work on optimism and subjective well-being has been done in the context of medical settings. Several projects have studied people having coronary artery bypass surgery. Several projects have also studied optimism in the context of treatment for breast cancer. Other studies have examined optimism in the context of *in vitro* fertilization, a procedure that helps people overcome fertility problems, and in the context of treatment for ischemic heart disease. Another project studied a group of cancer patients and their family caregivers. Family caregiving for a serious illness is highly stressful. In this study caregivers' optimism predicted less depression over time and less adverse impact of caregiving on their physical health.

The experiences of intense distress, hopelessness, and disengagement from effort have physical concomitants; so do positive emotions and engagement in positive efforts. A number of psychologists and others believe that these physiological responses can play a role in health outcomes, thus resulting in health outcomes that differ between

optimists and pessimists (Boehm and Kubzansky, 2012; Rasmussen et al., 2009). Such processes may influence a person's probability of getting a disease in the first place, they may influence the progression of diseases, and they may even influence mortality.

Studying Optimism and Pessimism

The easiest way to think about and measure optimism and pessimism is in terms of expectancies, asking people directly whether they expect outcomes in their lives to be good or bad. This approach is reflected in the life orientation test (LOT) and its successor the life orientation test-revised (LOT-R; Scheier et al., 1994). The LOT-R consists of a set of statements (e.g., 'I am always optimistic about my future,' 'I rarely count on good things happening to me' (reversed)) to which people indicate their agreement or disagreement on a multipoint scale. This measure yields a continuous distribution of scores. It is common to refer to optimists and pessimists as though they were distinct categories of people, but this is simply a verbal convenience. Almost never is a line drawn and people placed into two groups. People range from very optimistic to very pessimistic, with most being somewhere between.

There has, however, been some controversy about whether the optimism construct should be seen as one bipolar dimension or whether there are two separable dimensions, one pertaining to affirmation versus denial of optimism, the other pertaining to affirmation versus denial of pessimism. This controversy stems mostly from the fact that factor analyses of the LOT-R usually produce two factors, one marked by the optimistically worded items, the other by the pessimistically worded items. The core question in the controversy is whether or not this separation (a pattern that is quite common in measures that have both positively and negatively worded items) reflects a substantive difference. Some people believe the two sets of items should be kept separate, others disagree. Sometimes separating the item sets from each other has led to better prediction of outcomes, but not always. A number of projects trying to settle the issue have come to different conclusions.

For the sake of simplicity, in this article optimism–pessimism is treated as one dimension. Keep in mind, however, that in some studies what mattered most was the extent to which people endorse versus reject a pessimistic outlook; in other studies what matters most was the extent to which people endorse versus reject an optimistic outlook. In yet other studies, this issue did not matter at all.

Optimism and Coping

As indicated at the outset, the definition of optimism and pessimism in terms of people's expectations for the future links the concepts closely to a family of motivation theories. The most obvious reflection of motivation is how people behave. One place where behavioral differences between optimists and pessimists have been investigated closely is how they cope with adversity. The ways in which optimists and pessimists differ in coping resemble the differences in broad behavioral tendencies discussed earlier in the article. That is, people who are confident about their eventual success continue trying to move forward, even when the going is hard. People who are doubtful about being able to succeed try to escape the adversity by wishful thinking; they are drawn into temporary distractions that do not help solve the problem; and they sometimes even stop trying to do anything.

Differences in coping between optimists and pessimists that correspond to this picture have been found in a number of studies (for detailed review and *meta*-analysis see Solberg Nes and Segerstrom, 2006). Early studies examined student reports of both situational coping responses and general coping styles, and found that optimists appear generally to be approach copers and pessimists appear to be avoidant copers. Conceptually similar results have come from many subsequent studies.

Other projects have studied what coping strategies were used spontaneously by people in specific difficult contexts (for detail, see Carver et al., 2010). For example, a study of coronary artery bypass surgery assessed people's attentional cognitive strategies as ways of dealing with the experience. Before surgery, optimists more than pessimists reported already making plans for their future and setting goals for recovery. Optimists also focused less than did pessimists on negative aspects of the experience – distress and symptoms. Once surgery was past, optimists more than pessimists reported seeking out information about what the physician would require of them in the months ahead. There was also evidence that the positive impact of optimism on quality of life 6 months later occurred through the indirect effect of these differences in coping.

Another study looked at how women coped with treatment for breast cancer during the first year after diagnosis and treatment. Both before and after surgery, optimism related to coping that involved accepting the reality of the situation as one that must be dealt with, placing as positive a light on it as possible, and trying to relieve the situation with humor. Pessimism related to overt denial (reports of trying to push the reality of the situation away) and to giving up tendencies at each time point. The coping responses that were related to optimism and pessimism were also related to distress. Further analyses revealed that the effect of optimism on distress was largely indirect through coping, particularly at postsurgery.

There are many distinct ways to cope, and many ways to categorize these various responses (for review see Carver and Connor-Smith, 2010). A particularly important distinction is between engagement or approach coping – aimed at dealing with the stressor or emotions stemming from it – and disengagement or avoidance coping – aimed at escaping the stressor or emotions stemming from it. In their *meta*-analysis of optimism and coping, Solberg Nes and Segerstrom (2006) fit a range of specific coping responses from various studies into four categories. Optimism was positively associated with broad measures of engagement coping, and was about equivalently related to two subsets of engagement coping responses: those that were problem focused (e.g., planning, seeking instrumental support) and those that were emotion focused (e.g., cognitive restructuring, acceptance). Optimists also varied their coping responses according to what sort of

stressor was being confronted. They reported more problem-focused coping with controllable stressors (such as academic demands) and more emotion-focused coping with uncontrollable stressors (such as trauma). Thus, optimism predicted active attempts to both change and accommodate to stressful circumstances, in ways that reflect flexible engagement.

The pattern for disengagement coping was opposite that of engagement coping. Optimism related inversely to disengagement coping, and to both problem-focused disengagement (e.g., behavioral disengagement) and emotion-focused disengagement (e.g., denial, wishful thinking). Thus, as would be expected from the expectancy-value motivational viewpoint, the relationship of optimism to coping differed substantially between engagement and disengagement.

In sum, optimists differ from pessimists in stable coping tendencies and in ways of coping when confronting specific stressful situations (Solberg Nes and Segerstrom, 2006). Of particular note maybe the contrast between acceptance and active denial. Denial (refusing to accept the reality of the situation) means trying to maintain a worldview that is no longer valid. Acceptance implies restructuring one's perceptions to come to grips with the situation. Optimists accept that reality, whereas pessimists try to deny it as long as possible. It should be stressed that acceptance here does not mean giving up. Acceptance of the reality of a challenge, even something as severe as a fatal illness, has different consequences. By accepting that one's life is compromised (in the case of a fatal illness), optimists shift the parameters within which they will live the time they have left. Acceptance may actually serve the purpose of keeping the person goal-engaged and indeed 'life-engaged.'

Fostering and Interfering with Well-Being

The concept of coping with adversity broadens easily to include a variety of related content areas. A simple extension is to what has been called preventive or proactive coping, processes that proactively promote good health and well-being rather than just reacting to adversity. An interesting question is whether optimists take active steps to ensure positive outcomes in their future, as opposed to just waiting for those outcomes to occur. This would resemble problem-focused coping, except that it is intended to prevent a stressor from arising in the first place.

An example of how this might occur is seeking knowledge pertaining to areas of potential risk. For example, middle age is a time when a variety of health risks begin to become relevant to people's lives. Would you expect adults who are optimistic about life to make the effort to learn about such risks, or to just ignore the question? Perhaps surprisingly, people high in dispositional optimism have been found to actually know more about risk factors for heart attacks than people who are less optimistic. They seem to be taking steps to be prepared for potential challenges (for review of studies see Carver et al., 2010).

Proactive efforts in health promotion have also been studied among patients recovering from heart attacks. In this research optimism was associated with success in lowering saturated fat, body fat, and an index of overall coronary risk. Optimism was also related to an increase in exercise. In another study of coronary artery bypass patients, 5 years after surgery, optimists were more likely to be taking vitamins, eating low-fat foods, and be enrolled in a cardiac rehabilitation program. Thus, optimists do not seem to take for granted that everything will turn out fine without their own personal involvement. Instead, they seem to believe that they have opportunities to help produce those outcomes, which they should take advantage of.

It might seem paradoxical that people who expect good things to happen take active steps to make sure good things *do* happen. But experience presumably teaches people that their own efforts play an important part in many kinds of life outcomes. Optimists maybe more confident about their outcomes because they are more confident that their efforts will be successful. For that reason, they are quicker to engage those efforts when there is a need for them.

If optimists are persistent in trying to reach goals, then pessimists should therefore be less persistent and more likely to give up. There is, in fact, a variety of evidence of giving up tendencies among pessimists. These tendencies often have adverse consequences. For example, giving up may underlie excessive alcohol use, which is often seen as an escape from problems. Pessimists are more vulnerable than optimists to such maladaptive behavior.

Another study examined a different indicator of giving up the disruption of normal social activities. In that study (Carver et al., 2003), breast cancer patients rated illness-related disruption of social activities at several points after treatment. At each assessment, pessimism predicted more disruption, along with emotional distress and fatigue. When confronted with a health threat, then, pessimism can lead to a withdrawal from the social activities that are important to a normal life.

Optimism as an Engine of Resources

Health psychology has probably been the main arena for studying effects of optimism, but not all research on this trait comes from health psychology. The tendency among optimists toward persistent goal pursuit, their active coping with stressors, and even their better health, may make it possible for them to translate their short-term approach tendencies into the longer-term development of resources.

One kind of resource is socioeconomic. Although this topic has not been much studied with respect to optimism, the available evidence points toward correlations between optimism and two indicators of socioeconomic status (SES): education and income. In one large sample of first-year undergraduates, dispositional optimism before starting school predicted a significantly higher probability of returning for the second year (Solberg Nes et al., 2009). The dropout rate for pessimists was roughly twice that for the very optimistic. In a smaller study of law students, optimism before starting school predicted higher income 10 years later.

Interestingly, socioeconomic resources also predict the development of optimism over time. One study assessed parents' SES (by education level, occupational class, and employment status) among children who were either 3 or

6 years of age. The children were assessed 21 years later, at 24 and 27 years old. There was a significant association between initial parental indicators of SES and adult optimism 21 years later, even when adult SES was controlled. Thus, poor childhood socioeconomic circumstances lead to pessimism later in life.

Another important kind of resources is social capital. Optimists also benefit in this domain. For example, a study of how students coped with the challenge of starting college found that optimists experienced greater increases in their social networks across the first semester than did pessimists. Other research has also found associations between expecting positive outcomes in the future and having broader social networks.

Why do optimists have better social connections than pessimists? One reason is that optimists are easier to like than pessimists. Studies confirm that people are more accepting of someone who expresses positive expectations for the future and more rejecting of someone who expresses negative expectations. Another study found that social interactions with optimistic people are more positive than those with less optimistic people. In yet another study, pessimism among men about to undergo coronary artery bypass surgery predicted greater caregiver burden from their wives 18 months later.

Another contributor may derive from the fact that optimists tend to see things in the best light. It seems likely that this includes things pertaining to their relationships. This might make optimists more satisfied in the relationship even when things are not perfect. Consistent with this idea, one recent study found that optimists had greater relationship satisfaction than pessimists, a difference that was mediated by their perceptions that partners were very supportive of them. Of course, it maybe that partners of optimists really *are* more supportive than partners of pessimists, because optimists are easier to like and thus support. This study controlled for that possibility, however. Even with that control, optimists perceived more supportiveness in their partners than pessimists.

Yet another reason why optimism represents a resource for relationships maybe that optimists work harder (or work more effectively) at their relationships. This would be consistent with their greater engagement with high priority tasks. In a study bearing on this question (Srivastava et al., 2006), relationship partners first had a conversation in the laboratory about the area of their greatest disagreement. Then the couples rated both their own behavior and their partner's behavior during that interaction. From this was created an index of engagement (being a good listener, not criticizing, trying to understand the other's point of view). Optimists were rated as being more engaged than those who were less optimistic. A week later, the couples were asked how well the conflict they had discussed had been resolved. More resolution came from those who were more optimistic and that effect was partly mediated by positive engagement in the previous discussion.

Another recent project tested the idea that optimists would have an orientation to relationships that fosters effective problem solving, just as optimists engage in problem-focused coping when under stress. This project (Assad et al., 2007) studied married couples across a 2-year period. Participants completed measures of cooperative problem solving, both for themselves and for their spouses. They were also recorded while discussing their relationship. Raters coded the recordings for relationship quality and negative interactions. Optimism was associated with better relationship quality, with less negative interactions, and with higher levels of cooperative problem solving.

In sum, although there are relatively few studies of the role of optimism in relationships, the evidence that does exist is consistent in indicating that pessimists have a harder road than do optimists. Given the importance of close relationships to life, this represents yet one more area in which the optimist appears to have the advantage.

Is There a Downside to Optimism?

Thus far, it seems that optimists have somehow found the keys to a rich and fulfilling life. Compared to people who are more pessimistic, they experience less distress when they encounter adversity. They cope with difficult situations by remaining engaged in the goals and activities that the stressor is threatening. They engage in problem-focused coping when there is something to be done, and they engage in accommodative coping when the adversity simply has to be endured. Perhaps as a result of these differences in coping, they also have better health-related outcomes and better social connections, both broadly and in their close relationships. These properties sound quite adaptive. Optimists seem to have the kind of life most of us want.

Some have asked, though, whether optimism can potentially lead to problems in certain kinds of contexts. Consider problem gambling. Gambling can cost large amounts of money and create serious problems in work and relationships. Gambling is a context in which having expectancies of good outcomes and being highly persistent might be counterproductive. Indeed, research has found some worrisome tendencies regarding gambling among optimists. Optimists have more positive expectations for gambling than did pessimists and they were less likely to reduce their bets after poor outcomes. The people in that research were not people with actual gambling problems. But the evidence suggests the possibility that optimists maybe more likely to develop such problems than pessimists.

Another set of studies has asked whether the persistence of optimists can create problems because they fail to recognize what they cannot accomplish. More simply, maybe optimists do not know when they should quit. Certainly circumstances do exist in which people have to recognize that their goals are lost, and that the adaptive course is to turn away from them. Does the dogged persistence of the optimist prevent that from occurring?

One project on this question examined people's willingness to disengage from tasks on which they were failing (because the task actually was impossible). In one condition, there was no alternative task to turn to; in other conditions there was an alternative. When there was no alternative task to switch to, everyone persisted at the impossible task. When there was another task, optimism related to faster switching from the impossible task. In effect, optimists gave up on a task they

could not master in order to turn to a similar task that they *could* perhaps master.

Another question is whether optimism causes people to see only what they want to see and ignore threats. The first evidence suggested the opposite that optimists pay closer attention to information about health threats than pessimists, provided the threat is serious and is relevant to them. More recently, however, other researchers found the reverse effect. Other studies have tied optimism to an attentional bias toward positive over negative stimuli. Exactly, how to view the information available on this question is not clear. There do appear, however, to be at least some cases in which optimism has drawbacks or blind spots. It is not clear how circumscribed these cases are, but this doubtless will remain a topic for future work.

Cultural Issues

The description throughout this article has been relative coherent and internally consistent. It should be noted, however, that most of what is known about optimism comes from studies of North Americans, mostly of European descent. An important question is the extent to which the knowledge derived from these studies generalizes to other groups. The information on that question is limited, but so far there have been both differences and similarities.

One difference is that Asians seem to distinguish more sharply than do European Americans between affirmation of an optimistic view of the future and rejection of a pessimistic view of the future. The cultures do not consistently report overall mean differences in optimism (Chang, 2002). Thus far, the evidence suggests that optimism and pessimism relate to quality of life outcomes in the same general way across cultures. This line of inquiry is likely to become more important over time.

Concluding Comment and Future Directions

A large literature indicates that people who hold positive expectations for the future respond to adversity in more adaptive ways than people who hold negative expectations. Furthermore, optimism appears to confer benefits in both intrapersonal and interpersonal domains, even in the absence of stress. Expectancies influence how people approach both stressors and opportunities, and they influence the success with which people deal with them. There are some ways in which the focused efforts and persistence of the optimist can go awry; however, these cases are few in number compared to the benefits that optimism seems to confer.

Research has linked optimism to better emotional well-being, more effective coping strategies, and even to better outcomes in several aspects of physical health. The advantages of optimism also appear to translate into the domains of interpersonal relationships: optimists are better liked than pessimists, they benefit from their natural tendency to see things in the best light, and they appear to engage more productive effort in the sorts of problem solving that keep relationships alive.

It is clear that optimism is an individual difference variable that plays a key role in human experience. From a personality psychologist's view, this variable displays the important role of individual differences across many domains of life. From a clinical psychologist's point of view, the evidence reviewed here represents an opportunity to learn from optimists, so that the processes that characterize their approach to the world can be taught to pessimists.

Abstract

Optogenetics is a term encompassing a wide array of tools and techniques for manipulating cell function with light. The effector molecules are genetically encoded, which allow manipulations to be targeted to select cell types. This selectivity, along with the high temporal resolution afforded by light actuation has several important advantages over traditional tools for altering brain function, and it enables novel types of experiments. Optogenetic tools presently enable scientists to drive changes in cellular excitability, intracellular signaling, gene expression, and receptor function. Here, we introduce the foundations of this important new technology, and discuss its rapidly expanding capabilities for enabling neurobiological research.

Studying the Brain and Behavior

Traditional Tools for Manipulating Brain Function

Scientists have long sought to understand the physiological basis of normal and abnormal brain function. A common approach has been to assess changes in behavior and/or neural activity following manipulation of targeted brain regions or systems. The ideal experimental tool would allow for reversible functional manipulations of well-defined neuronal populations on timescales ranging from the action potential to behavioral epochs. Historically, three classic approaches have been used to selectively manipulate brain regions in order to dissect the neural components underlying complex behaviors: lesions, pharmacological manipulations, and electrical stimulation. Each of these has unique strengths and weaknesses.

Brain lesions usually cause permanent loss of neural tissue in a target region, and therefore have poor cell selectivity and temporal resolution. Lesions are often generated with electrical current, mechanical damage, or injection of toxic substances into specific brain regions. This technique is well suited for discerning whether a given brain structure is necessary for particular behaviors or information processing. The long-term and irreversible nature of the brain damage can foster adaptation in other brain structures and secondary effects on behavior that can present confounds (Traversa et al., 1997).

Pharmacological approaches have led to tremendous advances in neuroscientific discovery. Although pharmacological approaches are usually reversible and often highly selective for particular mechanisms, such as specific receptors, they are usually not selective to particular cell types. The temporal precision of this technique is typically limited by the rate of diffusion or metabolization of the drug/ligand used. Therefore, many drugs used to study important brain mechanisms impact the brain over longer timescales lasting from dozens of minutes to hours (Kramer et al., 2013).

Intracranial electrical stimulation of neural tissue enables manipulation with high temporal resolution, and has provided a powerful tool for investigating behavior, plasticity, and functional brain connectivity. Despite its continued fundamental importance in brain research, electrical stimulation has several limitations. Stimulation current is not selective for cell types, it generates electrical artifacts that obscure neural recordings, and evokes both orthodromic and antidromic activity propagation by directly stimulating afferent fibers as well as efferent axonal projections.

These classic tools for manipulating brain function continue to contribute tremendously to neurobiological research. They are, however, limited by an inability to reversibly activate or inactivate a predefined cell type with high temporal resolution. In the late twentieth century, neuroscientists began to increasingly use genetic tools to overcome the problem of cell selectivity. These tools allow for removing ('knocking out'), reducing ('knock down'), or inserting ('knocking in') genes encoding for proteins of interest in well-defined neuronal populations in freely moving animals. This approach, however, still lacked high temporal precision. An augmented strategy was needed to actuate changes more rapidly. Actuation refers to the control of cellular function by biological or nonbiological components that transduce input stimuli into physiologically relevant outputs. An actuator is the physical substrate required to achieve such control. Scientists realized that light-driven actuators derived from photoreceptors and light-driven protein effectors (e.g., protein pumps, channels, and G-protein-coupled receptors (GPCRs)) would have several useful properties. In principle, they could be genetically encoded so as to be expressed in select cells and could provide highly precise, and reversible, cellular actuation on a timescale similar to the processes that govern neuronal excitability (Miesenbock and Kevrekidis, 2005).

The use of genetically encoded, light-driven protein effectors to trigger temporally precise cellular actuation in neurons defined the origin of the field of optogenetics (Zemelman et al., 2002; Lima and Miesenbock, 2005; Boyden et al., 2005). The versatility of the optogenetic technique has since expanded neuroscientists' ability to investigate the functional impacts of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.55060-0

specific cell types and mechanisms on downstream and upstream neural microcircuitry, their functional connectivity, and the collective neural dynamics that underlie behavior (Fenno et al., 2011).

Opsins and Optogenetic Technology

Historical Development

Opsins form a large and diverse class of light-sensitive proteins that are ubiquitous in all kingdoms of life. There are two classes of opsins: type I opsins encapsulate both light sensing and ion conductance properties within a single protein unit and are only found in microbes; type II (animal) opsins are GPCRs found only in eukaryotes where they are involved in vision and pigmentation.

Initial investigations of light-driven protein effectors for use in the field of optogenetics were focused on the metabotropic photoreceptors of vertebrate and invertebrate eyes, which possess innate light sensitivity and indirectly drive changes in cell excitability (Zemelman et al., 2002). However, the focus shifted to ionotropic microbial opsins because these exhibit fast, direct light-dependent ion conduction across the cell membrane. Genomic studies have continued to uncover more members of the microbial opsin family, each with different conductance properties that allow for either depolarization or hyperpolarization of the membrane potential, thus leading to excitation or inhibition of neural action potential generation. The predominant opsins currently in use include halorhodopsin (chloride pump), channelrhodopsin (nonselective cation channel), Mac (proton pump), and archaerhodopsin (proton pump).

The light-sensing component (chromophore) in microbial opsins is a vitamin A derivative termed retinal. In type I microbial opsins, incident photons cause the all-trans form of retinal to isomerize, which facilitates conformational changes in the opsin protein. This leads to increased ion transport across the cellular membrane by either opening an ion channel or by actively pumping ions. Once isomerized, the chromophore in the opsin must be replaced with a new molecule that is in the all-trans isomer form. A source of all-trans retinal is therefore required for opsins to function. Intriguingly, many scientists were initially hesitant to investigate the use of microbial opsins to elicit membrane potential changes in mammalian cells based on the false premise that mammalian cells lacked sufficient sources of all-trans retinal. This was exacerbated by misconceptions about the feasibility of microbial opsin expression, toxicity, and functionality in mammalian cells (Yizhar et al., 2011).

Important early breakthroughs in optogenetic research came from Miesenbock and colleagues (Zemelman et al., 2002, 2003; Lima and Miesenbock, 2005). This group targeted a ligand-gated ion channel to dopaminergic neurons in *Drosophila* (fruit fly) and injected them with an inactive, photosensitive ligand. Light stimulation then activated the ligand, which initiated action potentials in the dopaminergic neurons and evoked the fly's escape behaviors. Although an important landmark in optogenetic research, this method lacked the very high temporal resolution needed for rapid, reversible control of neurons on the timescale of individual action potentials (Boyden et al., 2005). Therefore, the search continued for direct light-driven control of the protein channels and pumps.

The discovery of the microbial channelrhodopsin-2 (ChR2) by Nagel et al. (2003) led to subsequent breakthroughs by Boyden, Deisseroth, and colleagues, who showed that ChR2 could be expressed in cultured mammalian neurons using a delivery vector based on a virus to insert DNA into these cells (Boyden et al., 2005). They also showed that these cells could be activated by light to reliably evoke action potentials. This work demonstrated an efficient technique for cell type-specific targeting and optical control with high temporal precision on a timescale roughly 1000 faster than all previous approaches, allowing for manipulations on a millisecond timescale, rather than seconds or minutes (Boyden et al., 2005). This work also countered prior misconceptions that microbial membrane proteins would be excessively toxic to mammalian cells, and showed that there were sufficient levels of all-trans retinal in mammalian cells for ChR2 function. These advances set the stage for the subsequent rapid development and adoption of optogenetic approaches for neuroscience research in mammals.

Methodology

The concept of the optogenetic technique consists of two general steps. First, light-sensitive proteins are selectively expressed in the cell type of interest using genetic techniques. Second, these opsins are actuated with light.

Methods for Targeting Specific Cell Types

The first step to obtain selective optical control is to identify a gene that is specific to the target cell type. For example, dopaminergic and noradrenergic neurons are the only cells in the brain that express the tyrosine hydroxylase gene. The expression of genes is controlled by regulatory DNA sequences called promoters; these are typically positioned upstream to the DNA sequence of the gene that is to be expressed. Promoters enable enzymes to convert downstream genes into messenger ribonucleic acid, which is then translated into protein. Promoter activity can be widespread among many different types of neurons (e.g., Elongation Factor-1 alpha) or it can be confined to a specific class of neurons (e.g., tyrosine hydroxylase). Restricting the expression of opsins to select cells can be achieved by restricting the expression of opsin genes by promoters that are unique to the cells of interest.

The predominant method for introducing DNA into neurons is the use of a 'vector' derived from an inactive form of a virus. The vector is loaded with a DNA 'construct' that contains several DNA segments with distinct functions. The DNA construct usually encodes (1) a promoter region to allow expression of the other DNA segments, (2) the opsin, (3) membrane trafficking sequences, and (4) a fluorescent reporter protein that is fused to the opsin to facilitate the visualization of opsin expression. The encoded opsin protein, tagged with a fluorescent reporter, is subsequently localized in the neuronal cell membrane of select cells. The fluorescent reporter remains in the cytosol and does not interfere with

opsin function. Robust optogenetic response requires sufficient time for opsin densities to reach optimal levels in the membrane, which is typically between 3 and 5 weeks post vector injection (Yizhar et al., 2011). This incubation period varies depending on the type of viral vector used and the nature of the preparation (whether *in vitro* or *in vivo*). The appropriate promoter and membrane trafficking sequences must be selected to ensure that the genetically encoded microbial opsins are expressed at adequate levels and localized in the membrane of the specific class of neurons that are targeted.

Viral vector DNA delivery methods are a versatile means of transfecting cells and result in greater genetic and anatomical specificity than other common cell transfection techniques (Fenno et al., 2011). Another important advantage is that viral-based vectors can introduce multiple gene copies into the host cell, which increases protein density and photocurrents, leading to more robust optical control. Such vectors do not elicit an adverse immune response, and are widely used in experiments with rodents and primates. The tissue type targeted and extent of gene expression within that tissue can be modified by varying the viral coat glycoproteins (thereby changing the serotypes) or by using different viruses. However, viral-based vectors are limited in the size of the DNA construct that can be delivered, which can restrict the use of large promoter sequences. Furthermore, some vectors integrate the DNA construct into the host genome, whereas others do not and remain in plasmid form; this impacts the duration of expression. Finally, opsins can be selectively targeted to cell bodies, surrounding axons, or both by selecting the appropriate type of viral-based vector.

Two commonly used viral vector types in optogenetic experiments are lentiviral (LV) vectors and adeno-associated viral (AAV) vectors. While both are able to transfect both dividing and nondividing cells, they have several important differences. LVs are able to integrate randomly into the host genome, thus providing the potential for more long-term gene expression than nonintegrative vectors such as AAVs. Although LVs are easily produced with simple in-lab tissue culture techniques, they are typically designated for work under Biosafety level-2 (BL-2) laboratory conditions. Consequently, the majority of optogenetic assays make use of different serotypes of AAVs, which can normally be used under BL-1 laboratory conditions. Both AAV and LV are derived from live viruses, but they have been engineered with numerous safety measures. These vectors cannot replicate and are not known to cause disease (Yizhar et al., 2011).

Attempting to use virus-based vectors to express a DNA construct encoding an endogenous promoter and the microbial opsins in a specific class of neuron is possible, but faces several challenges. First, it is impossible to package some large cell-specific promoters into current vectors. Further, several small cell-specific promoters have been reported to be too weak to drive the expression of microbial opsins (Tsai et al., 2009). Second, the target cell must have membrane receptors that are recognized by the viral vector for vector insertion to take place. An alternate methodology that overcomes these problems has been adopted from genetic engineering techniques. Animals have been engineered with a permanent genetic modification to introduce a gene encoding a protein that is not present in wild-type animals (Arenkiel et al., 2007). These 'exogenous' genes can be expressed robustly in select cell types using genome modification approaches that do not depend on viral-based vectors, and therefore avoid their limitations. The predominant strategy is to use an exogenous enzymatic protein called cre recombinase as a 'driver' for functional opsin expression in the animal brain. Many rodent lines expressing cre recombinase in specific neuronal cell populations have been generated (Gong et al., 2007; Witten et al., 2011). Vectors carrying novel DNA constructs whose expression is dependent on cre recombinase can then be injected into a 'cre driver' animal's brain. The novel DNA construct is then only expressed in neuronal cells containing cre recombinase. Consequently, the cre driver lines are useful for functional opsin expression for several reasons. First, they allow the experimenter to select animals with cre recombinase in select cell types, and restrict the targeting specificity of the opsin by choosing an appropriate location for the vector injection. Second, they circumvent the problem of identifying regulatory elements (e.g., promoters, enhancers) of adequate size and sufficient functionality to fit in the viral envelope along with the opsin. These benefits allow researchers to optogenetically control many types of neurons using off-the-shelf vectors, which allow these techniques to be utilized by scientists with little molecular biology experience.

An alternative approach is to generate a transgenic line of animals that permanently express opsins in select cells (Arenkiel et al., 2007). This method has some drawbacks including low levels of expression by the endogenous promoters, and an inability to confine opsin expression to specific anatomical loci. The cre-driver approach is currently better in these aspects (Tsai et al., 2009; Witten et al., 2011).

Functionality

Biomolecular engineering and genomic studies continue to generate new opsins with a variety of characteristics including variation in the specificity of ion conductance, kinetics, and sensitivity to varying wavelengths of light. The functionality of opsins can be broadly divided in terms of their functional effect on the cell: direct activation, direct inhibition, bistable modulation, modulation of intracellular signaling, and altered gene expression.

Direct Activation

ChR2 was the first opsin to be used for direct activation of mammalian neurons (Boyden et al., 2005). When illuminated, it allows nonselective conductance of positively charged ions (cations), resulting in depolarization of the membrane and increased neuronal excitation. It is activated by blue light, although other related variants show sensitivity to a range of wavelengths corresponding to blue-green visible light (450–505 nm). Several variants of ChR2 have been produced in effort to tailor the functional characteristics of ChR2 to a variety of experimental uses, such as slower inactivation and changes in peak activation wavelength. For example, the H143R variant has an amino acid residue substitution that elicits larger photocurrents relative to the wild-type ChR2, although at the expense of having slower inactivation. A channelrhodopsin discovered in *Volvox carteri* called VChR1 is

another optically actuated cation channel used for excitation. Unlike ChR2, it has a peak activation wavelength that is shifted toward longer wavelengths (red-shifted), thus allowing use in parallel with ChR2 for separate optogenetic control of different cell types (Zhang et al., 2011).

Direct Inhibition

The most commonly used tools for direct inhibition are the outward proton pump archaerhodopsin (Arch) and the inward chloride pump halorhodopsin (HR). These are actuated by yellow-green light and yellow-red light, respectively. Both of these pumps have undergone mutagenesis to alter and/or improve their functional performance in inhibiting the generation of action potentials (Gradinaru et al., 2007). Whereas ChR2 is an ion channel conducting a depolarizing current, Arch and HR are ion pumps that generate polarizing currents and therefore inhibit action potential generation. Arch and HR variants are unable to generate photocurrents that are equivalent in magnitude to those generated by channels (e.g., ChR2). For this reason, functional inhibition during behavior therefore requires intense illumination (Zhang et al., 2011).

Bistable Modulation

Point mutation variants of ChR2 have been generated that enable bistable (on/off) control of the neuronal membrane potential. These ChR2 variants are termed step-function opsins (Yizhar et al., 2011). Brief illumination with blue light causes them to reconfigure to an active state in which they pass constant depolarizing current. Illumination with yellow light turns them to the inactive, nonconducting state. This approach allows neurons to remain responsive to native synaptic inputs rather than biasing neural activity by directly generating action potentials entrained with photo stimulation (Fenno et al., 2011).

Modulation of Intracellular Signaling

Rather than directly influencing membrane excitability, other types of opsins can instead interact with intracellular signaling cascades. For instance, rhodopsin is a eukaryotic type II opsin that is both a light-sensing protein and a GPCR. Such opsin-receptor (termed optoXR) chimeras based on the rhodopsin architecture have been generated to effect temporally precise, light-driven modulation of a specific intracellular cascade *in vitro* and *in vivo* (Airan et al., 2009). Generating an entire library of optoXR chimeras will undoubtedly help to unravel biochemical mechanisms essential for plasticity, behavior, and neurological disease. Variants of the optoXR family can also been applied to study nonexcitable cells, extending the reach of optogenetics outside of the brain (Fenno et al., 2011).

Gene Expression

Recently, the optogenetic toolbox has been extended to include the optical control of the expression of endogenous genes in mammals (Konermann et al., 2013). This system can easily be customized to target many endogenous genomic loci, and no exogenous factors are required. The rapidly expanding toolkit for driving gene expression is described in more detail in a subsequent section of this article.

Light Delivery and Neural Interfaces

The opsins expressed in the brain must be activated with light. The requirements for light delivery differ significantly depending on whether an *in vitro* (brain slice or cultured neuron) or an *in vivo* (anesthetized or freely behaving animal) preparation is used. For *in vivo* preparations, two solutions are presently used: light emitting diodes are implanted in the brain, or optical fibers are used to direct light from sources external to the brain to the desired targets. The fibers can either be inserted through permanently implanted guide cannulae for the duration of each experiment, or a small piece of fiber attached to a connector (called a 'ferrule') is permanently implanted in the brain so that the ferrule is accessible on the skull. The permanent implant approach is more widely used because it involves less risk of tissue damage or infection that arises from repeatedly inserting materials into the brain after surgery.

Delivering sufficient light to activate opsins to deep brain structures faces several challenges. First, the optical fibers are typically at least 100–200 μm in diameter, which damage tissue around the region of interest and may increase immune response. Second, light intensity rapidly decays away from the fiber tip due to diffraction and absorption by neural tissue (Yizhar et al., 2011). This heightens the importance of proper surgical placement of the optical fiber, and prevents uniform activation of cells within a structure. An online tool is available for estimating light power density at a given distance from the fiber tip in neural tissue (www.optogenetics.org/calc). Third, light in the brain produces heat. The effects of light-induced heating on neural tissue have not been studied enough to draw any definitive conclusions regarding the significance of thermal changes in neural tissue. This potential concern, however, limits the use of optogenetic approaches to illumination with brief light pulses. This is particularly limiting for inactivation studies during behaviors that require more than a few seconds. These challenges necessitate control experiments in animals lacking opsins to account for effects of illumination on neural tissue (Yizhar et al., 2011).

Emerging Directions

Restricted Transgene Expression in Homogenous Cell Populations

With the precise temporal control and ability to target specific cell populations offered by optogenetics, researchers have been able to investigate the function of the brain in ways that were previously impossible. This is demonstrated in a recent study by Liu et al. (2012), who investigated fear memory recall and its effects on behavior in mice. Animals first underwent a fear conditioning paradigm using an auditory tone followed by a mild electrical foot shock. Once conditioned, the mice demonstrated a freezing motor response to the tone, which was indicative of the retrieval of fear memory. Liu and colleagues then showed that the fear memory could also be retrieved by direct activation of neurons in the dentate gyrus of the hippocampus by selectively activating a subset of neurons in this structure with ChR2. This study illustrates that the

stimulation of a population of neurons is capable of eliciting macroscopic behavioral changes. Additionally, the research showcases a novel modification of established transfection techniques to enhance cell specificity by coupling ChR2 expression only to neurons that are actively depolarizing. This allows the optical stimulation to only activate neurons that were active during the formation of the initial memory engram, despite being in a larger population of the same cell type. To accomplish this, Liu and colleagues used molecular methods to restrict expression of ChR2 to cells that expressed *c-fos*, a gene that is rapidly expressed following increased neural activation. This novel method allows for even greater specificity in optogenetic experiments by restricting ChR2 expression to active neurons within a larger homogenous population.

Targeting Neuron Projections

Another example of further refinements in optogenetic techniques for elucidating brain circuits and their direct effect on behavior is work from Tye et al. (2011). These researchers demonstrated that the optical stimulation of terminals in the central nucleus of the amygdala (CeA) originating from the basolateral amygdala (BLA) exerts an anxiolytic effect in mice. Two classic methods to assess behaviors associated with anxiety are the open field test and the elevated-plus maze. Anxious animals spend less time in the center of the open field and the exposed arms of the maze. When ChR2 was optically activated in the terminals from the BLA, mice spent more time in these areas, suggesting they were less anxious. Conversely, using the inhibitory HR to silence these same terminals led to a decrease in the open areas, which is indicative of increased, anxiety.

Perhaps the most interesting discovery in these experiments was that while the stimulation of ChR2-expressing projections from the BLA to the CeA reduced anxiety, this was not true when the cell soma located in the BLA that were the source of these projections were preferentially stimulated with light. Tye and colleagues tested this by beveling the light-delivering fiber cannula so that light was directed toward the cell bodies rather than the terminals. This simple modification permits an even more focused delivery of light so that only select parts of a neuron can be bathed in illumination.

Modifications to Receptor Function

Another recent approach has been to modulate the functionality of specific receptors. Here, protein channels or receptors are covalently linked to an exogenous photo-switchable compound. This photo-switchable compound is fused to a ligand such that illumination with light will trigger the ligand to act on the protein channel/receptor (Kramer et al., 2013). Similarly to cell type-specific targeting in the optogenetic technique, a viral-based vector is used to carry and deliver a DNA construct encoding the modified protein to select cells. For example, any of the numerous subtypes of the voltage-gated K^+ channel can be modified with a covalently attached photo-switchable 'blocker.' Illumination with light will cause the blocker to inhibit the channel (Kramer et al., 2013). Although this approach does not use opsins, it provides tools for functional studies of endogenous channels or receptors with high temporal resolution rivaling that seen in opsin based optogenetic experiments.

Other Emerging Directions

In addition to using light to alter the function of cells, new optogenetic tools are being developed for reading out the activity from large populations of defined cell types. These are based on genetically encoded fluorescent proteins that report intracellular or extracellular physiological changes (membrane potential, Ca^{2+} concentrations, synaptic transmission, and metabolite fluctuations) in genetically targeted cell populations (Carlson and Campbell, 2013; Akerboom et al., 2012; Dreosti et al., 2009). For instance, viral vectors can be used to express the Ca^{2+} indicating protein, $GCaMP_3$, to targeted cells in mouse hippocampus. Then, a miniature fluorescence camera can be used to image Ca^{2+} dynamics in hundreds of cells in a freely moving mouse, providing a measure of neural activity (Ziv et al., 2013).

Although light can rapidly actuate protein function, it is limited to small regions of tissue and to brief illumination times due to diffraction and heat. Light is therefore not ideal for actuating proteins that are distributed widely in the brain, or actuating over long behavioral epochs. An alternate approach is to use a ligand as the actuator. The primary technique for this type of actuation is called Designer Receptor Exclusively Activated by Designer Drugs (DREADDs). DREADDs use chemical ligands in lieu of light to activate genetically encoded GPCRs. This enables targeting of specific G-protein signaling pathways with effects on membrane excitability or initiation of gene expression widely in the brain of freely behaving animals over the course of tens of minutes (Rogan and Roth, 2011).

Conclusion

Optogenetics is a revolutionary new technology for manipulating and monitoring brain function that overcomes several key problems of traditional methods, namely low cell type selectivity and low temporal precision. This rapidly expanding set of tools allows for control not only of the membrane potential, but also of gene expression, intracellular signaling cascades, and receptor function. Undoubtedly, the optogenetic toolbox will feature prominently in future neurobiological research and lead to breakthroughs in our understanding of the neural underpinnings of animal behavior and disease states.

Oral and Literate Expression

Ruth Finnegan, Open University, Milton Keynes, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The phrase 'oral and literate expression' refers to verbalizd formulations communicated through speech and writing respectively. 'Oral' and 'literate' are often seen as contrasted or complementary (hence their joint treatment in this article), but the relations between them, even their juxtaposition, are matters of debate. Recent research focuses on their overlap, taking them as dimensions of a multiplex and socially mediated continuum that continues to evolve. This article provides an overview of their main manifestations, then considers issues of definition and approach to their study, and lastly, discusses recent research trends.

The phrase 'oral and literate expression' refers to verbalized formulations communicated through speech and writing respectively. 'Oral' and 'literate' are often seen as contrasted or complementary (hence their joint treatment in this article), but the relations between them, even their juxtaposition, are matters of debate. Recent research tends to focus on their overlap, taking them as dimensions of a multiplex and socially mediated continuum. This article starts with a short overview of their main manifestations, then considers issues of definition and approach, the application of these concepts in the current situation of changing technologies, and recent research trends.

Spoken and Written Expression in Human Culture

Oral Expression

The rich complexities of oral forms, long ignored in the scholarly focus on written expression, are now being increasingly appreciated and studied (for examples and discussion, see Amodi, 2006; Feld, 1990; Finnegan, 2012, 2013; Foley, 2002; Okpewho, 1992; Perks and Thomson, 2006). Their nature and functioning are not necessarily identical to those of writing. In many disciplines, from philosophy and sociolinguistics to anthropology and education, the focus has shifted away from treating oral forms as if they are written texts toward active speech processes, conversations, and discourse-in-context. As with written genres, so too there are oral (or speech) genres; for example, different styles are expected for political speeches, spoken prayers, or personal greetings. Oral expression uses varying permutations of human voices (speaking, singing, chanting, shouting), singly or combined, with generic conventions based on, for example, appropriate verbal and performance style for speakers, audiences, context, or purpose.

These forms of expression are deployed in manifold ways in innumerable formal and informal situations, from intimate interchanges to public rituals. Many oral genres typically involve speakers present at the occasion and transient performances (unlike the greater permanence of writing), but some are now also enacted over far distances through electrical and electronic technologies or stored and reproduced in audio-recordings. Like writing, they are both interwoven with human organization and creatively used by individuals for an infinite number of purposes (Duranti, 1997; Finnegan, 2013a).

In most cultures people single out certain oral genres for heightened attention (Duranti, 1997; Feld, 1990; Finnegan, 2012; Okpewho, 1992). Far from being crude, communal, or uncreative, as once supposed, 'nonliterate' formulations can be extremely sophisticated in both verbal exposition and performance. Examples include the magnificent oral artistries of the twentieth-century South Slavic epics, the lofty diction of Zulu panegyrics, the brilliant imagery of Somali 'miniature' lyrics, the deeply felt 'wept thoughts' of some South Pacific laments, or contemporary performance poetry. Oral genres such as narratives, myths, epics, eulogies, protest poetry, laments, love poems, oratory, and song-texts (themselves a form of lyric poetry) are variously found throughout the world, and also include condensed but sometimes highly artful proverbs, jokes, anecdotes, or after-dinner tales. These are often described as 'oral literature' and although the term is not wholly satisfactory (it underplays performance dimensions, for example) it usefully highlights their literary qualities; a few scholars prefer the neologism 'orature'. Their study has enabled a radical reassessment among scholars of the achievements of oral expression, once regarded as being without creativity or individually shaped verbal artistry, notably in the lyrics of popular music and in the cultures of Africa, Native America, or Oceania.

Expression in Writing

Through the ages humans have developed many forms of writing: systems for communicating relatively specific ideas through standardized and relatively permanent visible marks, conventionally ordered and interpreted. Many systems are based on close relations between written marks and speech sounds, conveyed through syllabic, consonantal, or, most familiar to Western readers, alphabetic symbols (phonographic systems). Others, such as the Chinese and Aztek systems, use visual signs, sometimes pictorially based, to represent meanings rather than sounds (variously termed logographic, ideographic, and/or semasiographic systems); these allow communication across language boundaries, notably in the far-spread Chinese script. Some scholars include within writing pictographic systems such as American hobo signs or Native American pictorial records of events; others prefer narrower definitions like 'visible speech' (DeFrancis, 1989; Mallery

1893). The classifications and boundaries of writing are thus not fully agreed, partly because most systems combine several principles and the relations between speech (and other) sounds and written signs are variable (Boone and Mignolo, 1994; Daniels and Bright, 1996; Ellingson, 1986; Harris, 2000; Van Leeuwen, 1999).

Writing appears in many different materials and forms, versatile enough to be turned to almost any of the multifarious purposes of human interaction. These include encapsulating, storing, and transmitting information; counting and accounting (sometimes seen as the origin of writing); formulating and extending memory; bridging space and time; and facilitating personal and artistic expression. Writing is also used in the formulation of recognized literary and religious works and their communication within and across human cultures. Western Europe, China, and the Islamic world are famous examples; but throughout history and, nowadays, in every area of the globe, writing has played powerful roles – for good or for ill – in large-scale organizations; in personal and group expression at every level; and in the human endeavor to transcend space and time. It is inextricably embedded in human social institutions, for example, in the educational, artistic, and organizational hierarchies of the modern West – but not only there (Barber, 2006; Barton and Hamilton 1998; Cavallo and Chartier 1995; Coleman, 1996).

The Concepts 'Oral' and 'Literate': Problems and Approaches

The distinction between oral and literate expression seems at first self-evident, familiar from phrases like 'the spoken and written word'. However 'oral' and 'literate' are complex and multiform concepts, both in their varying cultural manifestations and in the theoretical controversies surrounding them. They are all the more 'loaded' because they invoke emotive and far-reaching issues about the nature and history of human culture.

The terms themselves are awkward in English. 'Oral' mostly refers to what is spoken or uttered by the mouth, but it also sometimes refers to anything that is not written: the first sense excludes deaf signing and nonverbalized material culture, the second includes them; phrases like 'oral tradition' can thus be ambiguous. The term 'literate' partly complements 'oral' but is not precisely parallel and is sometimes replaced by the term 'written'. While it can readily be assumed that all members of a society normally gain some capacity to speak and hear, the skills of reading and (not necessarily the same) of writing are less widely distributed – though contrary to some presuppositions, many so-called oral societies also recognize training and expertise in particular forms of spoken art and forms that are proscribed to certain sections of society (Bauman and Sherzer, 1989; Finnegan, 2012, 2013a).

The referents and connotations of each term have also been channeled through a series of theoretical frameworks and questions. Many of these broadly match those elsewhere in the social sciences, successively dominated by, for example, evolutionist, diffusionist, and functionalist analyses; ideas of reflection; structuralism, poststructuralism, and post-modernism; and a variety of Marxist-inspired and cognitivist approaches. Each has it own 'fix' on the terms and their interrelationships. I have selected a few below to illustrate the contrasting and changing perspectives.

Romantic and Evolutionary Paradigms

Some interest in contrasts between spoken and written expression dates back at least to classical Greece but in more recent centuries the most influential model has posited a teleological progression in human history, from oral to written. Spoken and written forms are viewed as themselves distinct and as characterizing distinctive evolutionary stages, with writing destined to supersede the oral phase in the upward path to enlightened modernity. Complementing and partly overlapping this is a nostalgia about what was supposedly sacrificed in the process: a romantic glorification of that lost 'other'. Thus so-called oral cultures are visualized both as the valued repository of deep-seated, communal, and emotionally sensitive qualities, as well as a 'primitive stage' that modern peoples have left behind.

Consequences of Orality and Literacy

The *consequences* of oral and literate forms of expression attracted much scholarly and popular interest through the mid- and late twentieth century. Somewhat counter-intuitively this seems in practice to have been started off by the work on literacy, this in turn drawing attention to what before had just been presupposed as the 'natural' – and thus uninteresting – order of things. The British anthropologist Jack Goody argued from the 1960s that the functions and effects of literacy should be studied comparatively (Goody, 1968). Parallel questions were raised in history, sociology, and comparative literary studies, further reinforced by interest in development, economic 'modernization', educational applications, and the major comparative features of societal organization. Marshall McLuhan's writings on the media (1964) stirred popular imagination and intermixed with continuing evolutionary and romantic perspectives. The result was intensive discussion about the social and cognitive consequences of literacy. Among them were rationality; objectivity; the emergence of history, science and/or philosophy; secularism (but in other accounts religious obscurantism); political and religious control (or alternatively, freedom); modernization – the 'take-off' for economic development and/or imperial rule both in early history and the present; innovation; the transition from auditory to visual perception; bureaucracy; and individualism.

The suggested consequences between them thus spanned almost every feature associated either ideally or in practice with Post-Enlightenment Western society; and chimed well with narratives of the print-based Protestant Reformation and of the expansionist West disseminating literacy through its civilizing mission.

Most of this presupposed some independent variable from which these consequences flowed. Usually this was literacy, with orality being implicitly its more shadowy opposite. However just what this literacy comprised was less clear. Some of the posited effects occurred in some eras but not in others or were even mutually contradictory (e.g., literacy leading both to freedom *and* to oppression), so they could scarcely be

automatic results from some uniform entity. As in other areas of the social sciences, many analysts thus now speak more of 'implications' rather than 'unicausal consequences', and of 'possibilism' rather than 'determinism', recognizing that literacy takes many forms and is used differently in different settings.

The Orality–Literacy Debate

Linked to the interest in consequences was the so-called orality–literacy debate. This revolved round the question of whether there is some generalizable divide between oral and literate cultures, and/or between oral and literate minds.

On the one side were writers like Marshal McLuhan (1964, 1982), Goody (2000), and Olson and Torrance (1991), who not only strongly contrasted 'literacy' and 'orality' but often envisaged human history as a series of major changes – from orality, to writing, to print. Each stage was seen as having distinctive properties, with the 'Great Divide' between 'primitive' and 'civilized' marked by literacy. This resonated with evolutionary and romantic notions, carrying connotations of orality as primeval, emotional, and homogeneous, characterized by unchanging and communal tradition rather than individual creativity, as against the rationality, individualism, science, urbanism, modernity, and economic development associated with literacy. This in turn recalled the binary division between types of society envisaged by classic nineteenth and early twentieth century social theorists.

Other scholars argued that the basic question was 'over general', giving a spurious identity to multiplex notions (Boyarin, 1993; Finnegan, 2013b; Schousboe and Larsen, 1989; Street, 1993). They challenged the ethnocentric Western bias of the contrast and its implicit technological determinism. In their view literacy and orality are neither autonomous nor unitary. The practices of speaking and writing coexist, they are socially as much as technologically shaped, and cultural variations undermine sweeping generalizations.

A further twist came in McLuhan's (1964) and Ong's (1982) vision of electrical and electronic technologies as ushering in a new age of 'secondary orality'. This further linked to suggestions that the apparent bias toward vision in Western cultures, often associated particularly with Gutenberg's printing press, was now being redressed by new opportunities for audio-communication, and hence providing a greater role, once again, for oral expression. The position is complicated, not least because others propound a new 'visual turn', but computer technologies certainly open new opportunities in many directions. They also challenge older assumptions about oral forms being fleeting, evanescent, and essentially variable in contrast to the fixed, permanent, and authoritative properties of writing. Computer 'soft' text transcends that postulated divide and erodes yet further the once-confident distinctions (Danet, 1997).

The trend is now to take more account of diversity and change rather than generalizing about 'orality' or 'literacy' as supposedly uniform entities. But the question is constantly being recycled, sometimes by writers unacquainted with recent – or, indeed earlier – work, and still stirs both academic and popular interest.

Ethnographic and Historical Specificities

Many scholars now look instead toward empirical investigation of specific cases (Amodio, 2005; Barber, 2002; Bauman and Sherzer, 1989; Cope and Kalantzis, 2000; Danet, 1997). Here 'oral' and 'literate' turn out to be less hard-edged and autonomous than once assumed and to come in varied, culturally specific, forms. Speaking and writing intermingle in manifold genres rather than exist in monolithic and clearly separated form. The famous Greek epics of Homer, for example, were probably first composed and performed orally, but then transmitted in writing. Oral and written traditions are not independent streams, as once supposed; the same works sometimes appear in both modes and move between them (Coleman, 1996; Finnegan, 1992, 2013a; Henigan, 2012). Examples are national anthems, carols, well-known religious texts, 'urban myths', Hausa political poetry, and English-American ballads.

In classical and medieval Europe, literary works were commonly composed for the voice and 'published' by being read or performed aloud to an audience; comparable interplays of oral and written processes occur in sermons, plays, or conference papers today (Amodio, 2005; Coleman, 1996). Song lyricists have often used mixes of written and oral media to compose sung words and guide their performances. Similarly written formulations are related to oral practices in a huge variety of ways, from dictated transcriptions and performance scores to crib sheets, prompt books, or jotted notes. Radio and television broadcasts and the icons, graphics, and audio-messages of modern computers further blur the once-clear divisions (for discussion and illustration see Boone and Mignolo, 1994; Boyarin, 1993; Cavallo and Chartier, 1995; Fardon and Furniss, 2000; Jorholt, 2001; Van Leeuwen, 1999).

The notions of oral versus literate thus no longer appear definitive and clearly opposed because they so readily coexist at any given time (Finnegan, 2012; Hofmeyr, 2004; Julien, 1992; Peek and Yankah, 2004), nor are they seen as carrying already known attributes when applied to cultures, genres, or individuals whether now or in the past. Rather they emerge as broad and somewhat ill-defined terms covering a spectrum of varying practices and artefacts, resources which human beings draw on in a multitude of overlapping, merging, and intermingled ways.

Recent Insights and Future Directions

While the earlier approaches described above still carry influence, current research could be said to be characterized by four interrelated trends.

Multiplicity and Differentiation

Recent analyses continue and extend the interest in historically and culturally specific contexts. Scholars now seldom speak of purely 'oral cultures', recognizing not only the lengthy and geographically widespread interconnections between oral and graphic systems, but also the complex and shifting varieties of current spoken/written/electronic interactions. Multiple versions of writing have existed and coexisted both in the past and in more recently developed systems, like the little-known

but ingenious indigenous scripts of West Africa (Finnegan, 2012). A definition based on Western history and alphabetic writing is no longer accepted as universally valid (Cavallo and Chartier, 1995; Cope and Kalantzis, 2000; Street, 1993).

Unlike earlier models envisaging homogeneous patterns of *either* orality *or* literacy throughout a culture as a whole, recent studies explore how different groups or individuals use and/or conceptualize speech and writing in diverse directions, have differential access to them, and deploy them differently in different situations. Even within the same locality, different categories of people use writing (or, indeed, speaking) in different ways. Some can read but not write; others may be multiply literate in different languages or different genres, using them for different purposes; others again may specialize in particular forms. There are accepted social controls on who can speak, how, and where, as well as on the learning, practice, and purposes of writing (Duranti, 1997; Finnegan, 2013a).

The focus is thus now on the multiplex, localized, and differentiated ways that both speaking and writing are learned, valued, or practised according to, for example, gender, rank, religious or educational role, age, geographical area, ethnicity, or situation. Critical and postmodernist analyses emphasize that both ideologies and practices may be related to the exercise of power, and can divide as well as unite. These spill over into studies of popular culture and the contemporary media, and of the role of literacy in the ideologies and practices of imperialism (Cope and Kalantzis, 2000; Street, 1993)

Practices and Processes Rather Than Texts and Products

A further trend goes beyond models of oral and literate expression as forms of text. This partly dates back to work on performance by linguistic anthropologists, folklorists, and others from around but has intensified since the 1960s through more recent social science interests in process and practice (Bauman and Sherzer, 1989; Gerstle et al., 2005; Schechner, 2002). Many scholars have turned from studying fixed products, formal typologies, or even cognitive meanings, toward investigating everyday situations, intertextual processes, emotive experiences, and the diversity of socially mediated expectations about how people do or should communicate.

Such studies throw up the creative and diverse involvements of individuals in oral and written interaction, revealing something of the infinite inventiveness of human beings in the composition, enactment, and reproduction of verbal expression. Even in a single communicative situation, different individuals may be participating differentially, actively constructing the communicative process rather than merely forming a passive or homogeneous 'audience' for an already defined message. This can be applied to written forms too. Readers approach and interpret their material in diverse ways, with marked differences between cultures, historical periods, sectional groups, and even individuals (Boyarin, 1993; Cavallo and Chartier, 1993; Manguel, 1996). The reality lies there as much as in the ostensibly objective and enduring text.

The investigation of 'text' continues (notably Barber, 2007; Honko, 2000) but the term is now less often taken as a given. Rather it is approached as a multifaceted issue for exploration, opening up questions about, for example, the socially shaped ways in which actions and communications are, or are not, crystallized in verbalized forms; how these relate to one another and to other aspects of social life; and the diverse processes through which they are actively put together and experienced.

The Senses and Multimodality

This article started by defining the key concepts in terms of 'verbalized' expression. But current research increasingly emphasizes that verbal expression consists of more than words. Speaking uses uttered words, certainly, but also regularly relies on concurrent 'visual communication', through participants' bodily gestures, movements, and positioning. In writing there are images, significant layouts, and visual displays over and above signs representing speech sounds, and sometimes tangible, acoustic, and olfactory dimensions. The materiality of artefacts such as books or letters now attracts interest, both in new transdisciplinary approaches to material culture and because computer developments challenge older and established print forms; and in so doing raises awareness of properties previously taken for granted. The remarkable surge of interest in the senses has also valuably added to the analysis of both oral and written media by drawing attention not only to the visual and auditory dimensions but also the olfactory, tactile, musical, and dynamic features which so enhance – or, rather, constitute – both written and spoken expression (Finnegan, 2014; Howes, 2005).

Earlier ideologies positing the neutrality, universality, and transparency of print now themselves turn out to be culturally moulded and implicated in material artefacts, not just mental representations. The multimodality of most, perhaps all, oral and written expression is likely to form one revealing area of research in the future.

The Virtues of Ethnography

There is currently great interest not just in the importance of accurate ethnographies, but also their comprehensive grasp. This has valuable implications for the study of oral and literate expression for it means that rather than positing some divide or, at best, interaction or transition between the two (not that this is always irrelevant; see, for example, Amodio, 2005; Ricard and Veit-Wild, 2005) the emphasis is now on a full account of the many media, senses, and genres, with all their complexities and elusiveness, in a given cultural context (Barber, 2002; Barton and Hamilton, 1998; Fox, 2000; Henigan, 2012; Hofmeyr, 2004). In this context, verbal expression in all its forms seems to shade into the many other art forms of culture, an amazing spectrum from the pictorial, and static to the dynamics of the fleeting dynamic art forms (Finnegan, 2013b; Howes, 2005).

There are other perspectives on speech and writing but a virtue of focusing on the interrelation of oral and written expression, even on partially outmoded debates, is that it brings to the surface and challenges, some powerful but often-unacknowledged presuppositions. In doing so it opens doors to a greater appreciation of both the continuities and the multiplex powers of these primarily (but not exclusively) verbal resources of human expression.

Abstract

The present article provides an overview about major aspects of the psychology of oral health. These comprise oral health-related quality of life, oral health behavior, dental anxiety, psychological stress and oral health, psychological factors in chronic facial pain, and psychological factors in denture satisfaction and adaptation. It is concluded that psychosocial factors play a major role in nearly every aspect of oral health. Still, further research is needed, especially with respect to psychosocial interventions. Additionally, psychological expertise and modeling is often missing in studies assessing psychosocial aspects of oral health. A claim is thus made for more interdisciplinary approaches including the expertise of both dentists and psychologists.

Introduction and Overview

The human face and therein the mouth is one of the most significant areas of the body for a variety of major psychological functions. It serves as a region of mutual recognition of persons and thereby also defines identity not only for the social counterpart but also for the individual itself. It is most important in social communication both with respect to the ability to communicate emotions by facial expression and with respect to the articulation of speech and other vocal utterances. The human smile is a most important part of social communication and is characterized beneath other factors by the visibility of the teeth. The teeth may form in this context a major aspect of one's attractiveness. The lips and the oral cavity are also regions of intimate social contacts. They represent the most sensitive parts of the human body provided with the highest density of sensible nerves and a disproportionally high representation in the sensory cortex exceeding that of any other body region.

According to all these factors, oral health comprises an important part of human well-being. At the same time, oral ill health and its treatment may become a psychological challenge. The present article provides an overview over these and other biopsychosocial interactions in the area of oral health and disease. In particular, it deals with the psychological impact of oral health, psychological aspects of the prevention of oral disease, psychological obstacles to adequate oral care, manifestations of psychological problems in oral health, and psychological aspects of treatment failure. It concludes with a statement concerning future research and practice of oral health care under a biopsychosocial perspective.

Psychological Impact of Oral Health: Oral Health-Related Quality of Life

The research about and assessment of health-related Quality of Life (QoL) denotes a rethinking in the consideration of health and health-related issues, which found its most prominent manifestation in the definition of health by the WHO from 1946: "Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (WHO, 1948). According to this definition, well-being is an important outcome measure of health assessment and health-related QoL is considered an important aspect of this well-being. Health-related QoL has been found to be associated not only with somatic factors and severity of disease but also with environmental factors and factors of the person like coping, self-efficacy, anxiety, depression, and so on.

Soon after the introduction of the concept of health-related QoL, it became obvious that generic measures of QoL often miss disease-specific impairments. As a consequence, disease-specific instruments were developed, e.g., instruments to assess oral health-related QoL. The assessment usually comprises impairments with respect to oral health itself and treatment of oral disease (like gingival bleeding, facial appearance), oral functioning (like chewing, talking), environmental, social, and emotional outcomes (Sischo and Broder, 2011). They have been used to assess the impact of various oral diseases (e.g., caries) and the outcome of treatments aiming to reduce impairments due to chronic conditions like periodontal disease or tooth loss (Sischo and Broder, 2011). Research, for instance, found oral health-related QoL to be related to the extent and severity of periodontal disease and demonstrated nonsurgical treatments of periodontitis to increase oral health-related QoL while surgical treatment had a lower impact (Shanbhag et al., 2012).

Oral health-related QoL is also assessed to define treatment needs and priorities at a population level. It has been found to be reduced under conditions of dental anxiety, periodontitis, caries, HIV, and so on. Oral health-related QoL is also associated with age, ethnicity, and socioeconomic status, and social disparities with respect to oral health-related QoL have been unveiled (Sischo and Broder, 2011). In this context, it is important to note that these relationships are not always simple. There is, for instance, some research indicating that oral health-related QoL is sometimes worse in younger generations as compared to older ones despite the differences in oral care between these groups, which point into the other direction (Slade, 2012). Other studies found first-generation migrants to report better oral health-related QoL than second-generation migrants (Sischo and Broder, 2011).

Oral health-related QoL is thus a meaningful outcome measure for oral treatments and an important parameter for the

assessment of health-related impairments, which might even affect health policy decisions.

Prevention of Oral Disease: Health Psychology in Oral Care

Maintenance and rehabilitation of oral health depend to a great degree on patient behavior. The two most prevalent oral diseases, caries and periodontal disease, are considered to be avoidable in most cases if nutritional factors are considered, professional care (i.e., regular visits at the dentist) is provided and oral hygiene is maintained (Baehni, 2012). All three factors depend mainly on patients' behavior. Thereby, oral health becomes a matter of health psychology (Renz et al., 2008). Several investigations have linked oral health behavior to behavioral skills, dental knowledge, health beliefs, self-esteem, self-efficacy, reasoned action, and so on (Deinzer et al., 2005).

The majority of interventional studies in preventive oral health behavior have focused on oral hygiene. Nevertheless, research in this area is hampered by a lack of scientific evidence for both, the aims of oral hygiene behavior (i.e., what is proper oral hygiene; Baehni, 2012) and the ways how to establish it (e.g., how often teeth should be cleaned and which brushing technique would be the best; Muller-Bolla et al., 2011). If the aims of oral hygiene were perfect oral cleanliness; a recent German study demonstrated that students did not have sufficient skills to even come close to that aim: more than 60% of the tooth surfaces showed persisting plaque after thorough oral hygiene (Harnacke et al., 2012). Little research is, however, available both regarding the best oral hygiene techniques (Muller-Bolla et al., 2011) and regarding the best ways to teach these techniques. From a psychological point of view, the latter is a matter not only of health psychology but also of kinesiology as tooth brushing is a complex motoric task (Harnacke et al., 2012).

Irrespective of these yet unresolved research questions there is a large number of education programs in dentistry, which mostly address patients' knowledge about dental diseases and teach patients oral hygiene techniques. Still, the effectiveness of these programs tends to be low and short-termed, if at all (Renz et al., 2008; Baehni, 2012). Recent reviews have, therefore, demanded more theoretically driven research, incorporating insights from health psychology. Renz et al. (2008) reviewed the available literature on interventions based on psychological models aiming to improve adherence to oral hygiene instructions in periodontitis patients. They only found four papers meeting their research criteria. From these studies they conclude: "There is tentative evidence that psychological approaches to behaviour management such as the use of reinforcement, goal setting and the provision of feedback can improve oral hygiene and oral hygiene related behaviours" (Renz et al., 2008: p. 11). They conclude that more research of high methodological quality is needed, based on psychological models and theoretical frameworks. Similarly, Baehni (2012) state that empowerment of patients is needed in a sense of a comprehensive education and competence training with realistic aims and well-defined action plans. He underlines the social and psychological competences necessary for oral care professionals to meet these requirements.

Psychological Obstacles to Adequate Oral Care: Dental Fear and Phobia

Psychological competences of oral health professional are of special significance when it comes to the prevention of and dealing with dental fear and anxiety (DFA), dental phobia (DP), and dental behavior management problems (DBMP). DFA is defined as strong aversive feelings against a dental visit and/or treatment while DP is a severe type of anxiety fulfilling clinical criteria of a phobic state. DBMP comprise uncooperative and disruptive behavior during the dental treatment. The prevalence of both DFA and DBMP in children and adolescents is estimated at approximately 9% (Klingberg and Broberg, 2007; Zhou et al., 2011). It is important to realize that both conditions do not necessarily coincide. In adults, the prevalence rate for DFA is estimated at 20%, as opposed to DP with 5% (Wide Boman et al., 2013). Several instruments have been developed to assess DFA in children, adolescents, and adults (Porritt et al., 2013; Wide Boman et al., 2013).

Considering the psychological significance of the mouth and the oral cavity mentioned in the introduction, reluctance to dental treatment is a natural response to a condition where intimate barriers are violated. Dental patients are exposed to a situation, which induces unpleasant feelings in several aspects. They are positioned in a supine position in a chair with usually no way to escape. This results in a feeling of loss of control. Furthermore, the dental professionals approach one of the most intimate regions of the body. Finally, dental treatment may be associated with pain or at least uncomfortable sensations and noises either due to the treatment itself or, e.g., the injection of anesthetics. Additionally, the dental practice is an environment of outstanding salience as it differs from most environments of daily exposure. These factors, the salient environment and the uncomfortable experiences, are best suited for classical conditioning. Thereby, while DFA may be a natural response in the beginning it easily transforms into a classically conditioned response, which emerges even in the absence of the unconditioned stimuli. The dental setting is, however, not only a situation easily being associated with physical threat. It is also a place where embarrassing situations are likely to occur, if, for instance, the dentist comments on oral hygiene.

Dental anxiety often results in avoidance of dental visits and treatments and thereby in reduced dental care, which again enhances dental problems and thereby DFA (Armfield, 2013; Wide Boman et al., 2013). It is thus pivotal for maintenance of oral health to reduce DFA in its very early stages. Zhou et al. (2011) reviewed studies analyzing the effects of dental staff behavior on child dental anxiety and behavioral problems. The few studies available do not allow for firm conclusions. Still, they give some hints that empathic communication, clear-cut and specific instructions, and appropriate physical contact in combination with explanations and verbal reassurance help to reduce both DFA and DBMP. Applied on their own, explanations, reassurance, or physical contact appear to be of low efficiency.

Several groups have also analyzed the effects of treatment programs aiming to overcome DFA and DP in adults. A recent review found interventions based on behavior therapy or cognitive behavior therapy to be effective in reducing dental anxiety and increasing patients' acceptance of dental treatment though the quality of the studies was moderate to low (Wide Boman et al., 2013). Interestingly, this psychological approach appeared to be more effective than a mere physiological approach like sedation during treatment.

Manifestation of Psychological Problems in Oral Disease: Periodontitis, Bruxism, and Orofacial Pain

While dental anxiety is a psychological problem immediately related to dental treatment and its setting, other less specific psychological problems might affect oral health as well. Among them is psychological stress. Gingivitis and periodontitis are the most prevalent dental disturbances in adults. Persisting dental plaque adjacent to the gingival margin induces an inflammatory response of the gingiva called gingivitis. Plaque removal results in a restitutio ad integrum in that stage of the disease. However, complete plaque removal is hardly ever achieved by the dental patient (Harnacke et al., 2012). Gingivitis may persist over long times without any further complications. But in many cases it progresses from a localized inflammation, affecting the gingiva alone to a more widespread infection of the gingiva and the adjacent periodontium, a periodontitis. The result is an irreversible inflammatory destruction of desmodontal fibers and the alveolar bone, both supporting the tooth to remain at its place. Thereby, tooth loss is the final consequence of untreated periodontitis.

Psychological stress has been considered to be an etiological factor in the development of periodontal disease (Rosania et al., 2009). Both, animal experiments and correlative human studies show relations between psychological stress and alveolar bone loss (Rosania et al., 2009; Akcali et al., 2013) and stress has been considered to explain at least some of the socioeconomic disparities with respect to periodontal health (Thomson et al., 2012). Several mechanisms have been discussed as potential explanation for these relationships (Preeja et al., 2013), among them immune-regulation and oral health behavior, which both have indeed been found to be altered under stress by our and other groups (e.g., Weik et al., 2008; Deinzer et al., 2005; Thrombelli and Farina, 2013). Though, it is now widely accepted to consider psychological stress as a risk factor for periodontal disease, intervention studies aiming to ameliorate adverse stress effects as an adjunctive approach to periodontal treatment are missing so far.

Chronic orofacial pain is another condition often believed to depend on more general psychological functions than to be a mere representation of a physical disorder. Orofacial pain comprises four symptomatic groups: temporomandibular disorder, burning mouth syndrome, atypical facial pain, and atypical odontalgia, i.e., tooth ache. All disturbances have in common that they cannot be explained merely by physiological findings. Often, patients complain about other yet unexplained physical symptoms as well (Aggarwal et al., 2011). Major symptoms include difficulties to open the mouth and sensations as if the teeth would not fit together. Medical interventions are often invasive in that they induce irreversible alterations of the stomathognathic system, e.g., by altering the occlusion in excavating disturbing occlusal contacts. Still, these and other medical interventions appear to have little effect, if any (Aggarwal et al., 2011). Several studies have investigated psychological factors potentially involved in these conditions. Perceived pain control, self-efficacy, and somatization were found to be psychological correlates. Behavioral factors may also be important, e.g., overactivity due to stress and anxiety, which result in enhanced muscular activity and teeth clenching, which in turn induce pain. Pain may then lead to fear-avoidance behavior impairing the functionality of the whole system (Aggarwal et al., 2011). Indeed, bruxism is considered a major risk factor for temporomandibular disorder. Bruxism is a motor disorder of the stomathognathic system resulting in clenching or grinding at day and/or during sleep. It results in disturbances of the stomathognathic system including tooth wear, muscular tensions, and disturbances of the temporomandibular joints. As potential etiological or maintaining factors for this disturbance, overactivity of dopaminergic systems is currently discussed, as are psychosocial factors. With respect to the latter, it appears mandatory to differentiate between sleep-bruxism and bruxism during daytime. While the latter clearly appears to depend on psychosocial factors, results concerning the former are less definitive (Manfredini and Lobbezoo, 2009). This may be, however, also due to the fact that it is much more difficult to diagnose sleep-bruxism, which would require polysomnographic recordings. Awake-bruxism appears to depend on emotional tension (e.g., stress, anxiety) and some personality factors and behavioral styles related to emotional tension (e.g., trait anxiety, anger-in-behavior, emotional coping), and its prevalence is enhanced in some mood disorders (Manfredini and Lobbezoo, 2009). Though bruxism not always results in orofacial pain, it is considered to be a major risk factor for temporomandibular disorder. The latter has been addressed in a variety of psychosocial randomized controlled trials (RCTs). Though the majority of these studies had a moderate to high risk of bias they provide weak evidence that cognitive behavioral interventions might be helpful in the treatment of temporomandibular disorder. This is remarkable considering that mere physiological treatment strategies tend to fail in these patients (Aggarwal et al., 2011). Interestingly, RCTs on the effects of psychosocial interventions for chronic orofacial pain appear to have focused on temporomandibular disorders and neglected the other conditions belonging to this field of oral health disorders (Aggarwal et al., 2011).

Psychological Factors in Treatment Failure: Dentures and Denture Adaptation

As mentioned in the introduction, the face and the mouth form an important part of human identity. Losing one's teeth can thereby become a psychological challenge and dentures are thus provided not only to overcome functional but also psychological and social problems related to edentulism. Indeed, prevalence of edentulism remains high irrespective of improving dental care because increasing live expectancy. Endentulsim is a chronic condition resulting in a variety of

impairments and in functional loss, for instance, with respect to eating, speaking, and social interaction in general. It is accompanied by a loss of alveolar bone, reduced support of soft tissues and facial musculature, and reduced masticatory force, which results in a functionality of mastication of 1/4 to 1/7 of that of a dentate adult (Roumanas, 2009). While the majority of patients are satisfied with their dentures, fewer than 10% (Roumanas, 2009) or between 10 and 20% (Carlsson, 2009) are dissatisfied. Though there is some correlation between patients' complaints and the objective quality of the denture or anatomical characteristics of the patient, these associations are far too small to explain patients' satisfaction or dissatisfaction (Carlsson, 2009; Roumanas, 2009). Typical complaints comprise instability of the denture, pain, difficulties in mastication, and aesthetics. With respect to the last, there is often a mismatch between patients' and dentists' ideas of what would be a good aesthetic result (e.g., when dentists chose a tooth color corresponding to patients' age while patients' prefer a brighter teeth color, which the dentist would judge as unnatural) (Roumanas, 2009). In an attempt to better understand factors predicting patients' satisfaction with their denture, several studies have been conducted. These indicated that patients' previous experiences and expectations are important predictors (Roumanas, 2009). Personality has also been found to be an important predictor, and a recent longitudinal study found neuroticism to predict patients' dissatisfaction even 2 years after they had received their denture (Roumanas, 2009; Fenlon et al., 2007). Another factor considered of high significance is the dentist–patient interaction and it has been suggested by several reviews that this factor is even more important than the 'technically perfect denture construction' (Carlsson, 2009). Again, however, intervention studies aiming to facilitate patients' satisfaction by psychosocial interventions appear to be rare.

Concluding Remarks

This short overview of psychological aspects of oral health is not comprehensive in that not all relevant areas of oral health and dental treatment related to psychological factors are covered, due to space limitations. For example, special problems of orthodontic treatment of adolescents, oral cancer and its psychosocial consequences, implant failure, and stress as a predictor, could not be discussed here. Still, this overview leads to some conclusions, which hold true for these and other areas of psychodental relationships as well.

- First and foremost, the dentist–patient relationship plays a pivotal role for nearly every area of oral health. A qualitatively good and empathic relationship serves not only as an ice-breaker and makes the interaction between the dentist and patient more comfortable. It also has a significant effect on oral health outcome.
- Second, psychological factors affect nearly every aspect of oral health. Patients' personality, their learning history, previous experiences, expectations, and current stress and strain may in some areas explain even more variance of oral health conditions than physical factors.
- Third, it is for these reasons that psychosocial knowledge and competences of the dentist are considered invaluable for qualitatively high dental care.
- Finally, though there exists some research on psychodental relationships, studies of high methodological quality and with good psychological foundation are sparse. Further research providing better scientific evidence is needed. More interdisciplinary approaches including the expertise of both dentists and psychologists would be helpful to fulfill these requirements.

Abstract

Oral history is a versatile research method that can be used in different ways and for different purposes. In this article we examine, first, the definition and origins of oral history and its relation to memory and processes of remembering; second, we offer a theoretical background to the study of oral data and a methodological exploration of oral history research; third, we provide practical information and advice on how to prepare for and conduct an interview. The article concludes with a brief discussion of recording equipment, ethical issues and details on the archivization, and dissemination of oral data.

Introduction

Attempting to define oral history, Donald Ritchie (2003) once said that oral history "collects memories and personal commentaries of historical significance through recorded interviews". However, oral history is 'too dynamic and creative a field' to be entirely captured by a single definition (p. 19). Similarly, Bruno Bonomo (2013) identified two ways of defining oral history: on the one hand it refers to oral traditions, for example in non-Western societies and indigenous cultures where tradition is transmitted orally from one generation to another, but which are also used to share family stories; on the other hand, 'oral history' refers to a method of historical reconstruction of the past which is based on oral sources (Bonomo, 2013: pp. 13–14). These have made important contributions to our understanding of the nature and meaning of oral history accounts (Thomson, 2006: p. 51). It may thus take the form of eyewitness evidence about the past, but can also include myths, songs, and stories passed down over the years by word of mouth. Furthermore, while oral history is an exceptionable way of preserving the knowledge and understanding of older people, it can also be used to engage with younger generations. Hence it contributes to a better understanding of both the past and the present. Nor should we ignore the fact that oral history is a highly interdisciplinary research area which links to other areas of research, such as sociology, folklore studies and anthropology, although the relationship between the disciplines has varied in different parts of the world (Thomson, 2006: p. 51; Evans, 1972: p. 56). Finally, oral history interviews can be used for a variety of purposes including for academic research, publication in a radio or video documentary, in museum exhibitions or posted on the Internet (Ritchie, 2003: p. 19).

In short, oral history is a versatile research method that can be used in different ways and for different purposes. In this article we will examine the definition of oral data and the relation of oral history to memory and historiography, before moving to an historical, theoretical, and methodological exploration of oral history research.

What Is Oral History?

Historian Lynn Abrams (2010) describes oral history in terms of a 'catch-all term' which reflects, on the one hand, the process of conducting and recording interviews; on the other hand, it is the very product of that interview, and as such it is both a research methodology and the result of that research process (p. 2). Indeed, the process of interviewing cannot be disconnected from the outcome of the interview (p. 3), as oral data are not simply 'produced' during the interview: this happens in the context of a communicative event, which strongly determines what and how it is remembered (Bonomo, 2013: pp. 23, 25). Hence the oral history interview reflects a performance and an act of narration, where the interviewee constructs a sense of self through the telling of stories (Abrams, 2010: p. 35). However, oral history is not a monolog but a dialog, where data is produced through a 'discursive weaving' between two or more individuals (Bonomo, 2013: pp. 25–26), as we shall see.

A History of Oral History

Historians have, since ancient times, relied upon eyewitness accounts in the creation of historical data. During the Renaissance, however, humanist scholars began considering written documents in the reconstruction of the past (Bonomo, 2013: p. 19). With the advent – in the nineteenth-century – of Positivism and the development of a discipline of academic history, archives and documentary material became the primary sources of research, and oral evidence was marginalized (Thompson, 2000: pp. 25–81; Ritchie, 2003: pp. 19–21; Sharpless, 2006: pp. 19–20; Bonomo, 2013: p. 19). It was not until the 1940s that the modern practice of oral history developed. Ronald Grele (2006) states that the attitudes and traditions within which it did reflected the tension between those who saw oral history as an archival practice and those who envisioned it as social history, and these were geographically specific: in the United States, oral history originated in archival projects while the European introduction to oral history was through the work of social historians (p. 44). Consequently,

historians in England led the way in documenting lives of ordinary people, as opposed to Americans who tended to focus on elites.

Oral history in the modern form of audio recordings has its origins in the work of Allan Nevins at the University of Columbia (Thomson, 1998: p. 581). Nevins began to record the memories of 'persons significant in American life' in 1948. He was the first to initiate a systematic and disciplined effort to record on tape, preserve, and make available for future research recollections deemed of historical significance. While working on a biography of President Grover Cleveland, he found that Cleveland's associates left few of the kinds of personal records that biographers generally rely upon. Nevins thus came up with the idea of conducting interviews with participants in recent history to supplement the written record.

In contrast to Nevin's 'great men' approach, George Ewart Evans (1972) – the pioneer of oral history in England – collected memories of life and work in Suffolk villages, where "the old survivors were walking books" (p. 57). These were published in *Ask the Fellows Who Cut the Hay* (1956). Alistair Thomson (2006) states that oral history was an essential source for the 'history from below' approach fostered by politically committed social historians in Britain, such as Evans, from the 1960s onward (p. 52). Paul Thompson, for example, was a social historian at the University of Essex who played a leading role in the creation of the British Oral History Society in the early 1970s and the subsequent development of an international oral history movement from the end of that decade.

Within this developing international movement, oral historians approached the collection, analysis, and dissemination of oral history in different ways. Graham Smith (2010) notes that in broad terms, while oral historians in Western Europe and North America have often focused on issues of identity and cultural difference, oral historians in Latin America and Eastern Europe have tended to pursue more overtly political projects. Ritchie (2003) states that worldwide political and social changes during the last few decades of the twentieth century confronted historians with the inadequacy of archival documentation. He argues, for example, that newly emerging nations in Asia and Africa found that the written documents reflected the views of former colonial masters, and used oral history to revive buried national identities (p. 23). Indeed, decolonialization processes in the 1950s led to the development of an interest in African studies where oral history research and anthropology merged, as in the influential works of anthropologist and historian Jan Vansina (Abrams, 2010: pp. 25–26; Bonomo, 2013: p. 48). Similarly, when the Soviet Union dissolved, a wave of autobiographical works were published as Russian and European oral historians sought to reexamine and rewrite their history by collecting personal testimony suppressed under Communist regimes (Bonomo, 2013: p. 67). Last, in recent years Brazil and Argentina have also witnessed a boom in oral history projects, to record the experiences of victims of military dictatorship and state terrorism (Ritchie, 2003: p. 23; Bonomo, 2013: p. 68).

Despite these valuable contributions to the historical record, oral history has nevertheless come under criticism: the speaker's personal knowledge has been held to be less reliable than written documents. Oral history is indeed reliant on memories, usually of older people, which are criticized for being sentimental, vague, inaccurate, and biased. Yet, as Elizabeth Tonkin (1992) argues, oral history is not either intrinsically more or less likely to be accurate than a written document: the latter are often no more than orality recorded (pp. 113–114). In addition, Alistair Thomson (2006) has demonstrated that oral historians have developed their own standards to assess the reliability of oral memory, for example, by learning from social psychology and anthropology how to determine the bias and fabulation of memory, the significance of retrospection, and the effects of the interviewer upon remembering (p. 54). Furthermore, from the late 1970s imaginative oral historians such as Luisa Passerini, Alessandro Portelli, and Michael Frisch have turned these criticisms on their head and argued that the so-called unreliability of memory was also its strength, and that the subjectivity of memory provided clues not only about the meanings of historical experience, but also about the relationships between past and present, between memory and personal identity, and between individual and collective memory (Thomson, 2006: p. 54).

This 'rehabilitation' of oral history continued in the 1980s, with the end of the 'grand narratives' as theorized by Jean-François Lyotard (1984), the revival of the narrative element in history writing, and the so-called linguistic turn (Bonomo, 2013: pp. 64–65). Connected to this is the fact that memory production in the 1980s became more focused on the analysis of collective traumatic events such as the Holocaust and on the survivor's authority as a witness (Bonomo, 2013: p. 37), symbolized in Annette Wievorka's definition of *The Era of the Witness* (1999), or what Thomson (2006) has defined a "biographical era" (p. 57).

Over the past two decades, finally, oral history has largely been accepted as a research methodology: it is practiced both in academia and in the public sphere, and is represented by a variety of associations and societies across the world. It has gained a particular value in processes of community building and reconstruction. As Lynn Abrams (2010) has justly observed, oral history "is one of the few ways by which those who have traditionally been silenced in History may be heard" (p. 24). Similarly, Alistair Thomson (1999) argues that oral history gives a voice to the voiceless, such as women, workers, ethnic minorities, indigenous peoples, and marginalized groups, and enables historians to investigate underresearched areas of history such as the family and private issues. Hence it is able to provide information about everyday life and give insights into the mentalities of what are sometimes termed 'ordinary people', offering data that simply cannot be drawn from more traditional sources (p. 291). Oral histories also eloquently make the case for the active agency of individuals whose lives have been lived within deeply constraining circumstances. In other words, oral history can open up new views of the past. For in an interview the voice of the narrator literally contends with that of the historian for control of the story. Recounting the experiences of everyday life and making sense of that experience, narrators turn history inside out, demanding to be understood as purposeful actors in the past, and talk about their lives in ways that do not easily fit into preexisting categories of analysis.

Memory and Remembering

There are several difficulties attributed to the use of oral data, due to the way in which people remember. Memory can, for example, be distorted by external constraints. It is also selective, as people often recall things that correspond with the image of themselves that they are trying to present. In his interviews with Australian First World War veterans, Alistair Thomson (1994) found that his respondents remembered events in such a way as would prove acceptable accounts of their war service to their present selves. When asked about their enlistment, for example, the veterans described reasons that were not untrue but which were angled to reflect the image they wanted to present (Thomson, 1990: pp. 27–31).

Memories are also subject to self-censorship, as is particularly evident in memories of Nazi Germany. People cannot remember events without benefit of hindsight as memory is embedded in present experience. Thus Michelle Mouton and Helena Pohlandt-McCormick (1999) argue that Germans do not suffer from collective amnesia, but from a collective revision of memory (p. 43). In order to deal with the horrors of war and the guilt associated with the genocide committed during the Nazi regime, they try to create an acceptable memory. Many of the German women interviewed by Mouton and Pohlandt-McCormick initially referred to the impossibility of acting against the Nazis, as this was a sanctioned way to remember the past (pp. 43–44). However, during the course of the interviews it became clear that several of the women had supported National Socialism at the time. The women seemed to contradict themselves, but this was not to be regarded as their trying to present misleading pictures of their pasts: they felt compelled to construct an interpretation of their past acceptable to the present climate. When using oral data the complexity of people's memories must therefore be observed.

Another good example of the complexities of remembering is the death of Italian steel worker Luigi Trastulli, shot by police during an anti-North Atlantic Treaty Organization (NATO) workers' rally in 1949. In what is perhaps the most cited article in the literature of oral history, Alessandro Portelli (1991) brilliantly demonstrates why oral accounts of this incident routinely get the date, place, and reason for Trastulli's death wrong. Narrators manipulated the facts surrounding this tragic incident to render it less senseless and more comprehensible to them. Although oral historians do attempt to get the story straight through careful background research and informed questioning, they are ultimately less concerned with the vagaries of individual memories than with the larger context within which individual acts of remembering occur, or with what might be termed social memory. As Portelli argues, "errors, inventions, and myths lead us through and beyond facts to their meanings" (p. 2).

Elizabeth Tonkin's statement about people speaking in genres brings us to another characteristic of oral history. 'Doing an interview' is an oral genre, which conditions how people tell their story as they have a model of what is expected of them in their head. They therefore use a mode of storytelling they think is suitable in this context (Tonkin, 1992: pp. 50–65). People also use narrative genres as a way of structuring their accounts. In her study of British women's lives during the Second World War, Penny Summerfield (1998) found that women adopted certain roles in which to present their war service. She showed how the women she interviewed about their experiences of the war principally adopted two narrative models: the stoic and the heroic (pp. 87–99, 284–285). In other words, some remembered their experiences as war heroes or as active participants in the shaping of events, with their narratives constructed to exemplify this, while others presented themselves as passive victims of the war. Seen in the context of a range of other sources, oral history can, then, reveal the complex ways in which women and men compose their narratives in order to reconcile ideals of femininity and masculinity with the reality of their own lives (Davies, 1992: p. 55).

Finally, what respondents do not say can be as important sources of information as what they do, and even when the facts they give us are wrong, the reasons why they do so can tell us something about the society at the time they are describing, and that of the present. Luisa Passerini (1987), for example, analyzed the silences and inconsistencies in Italian working-class memories of Benito Mussolini's interwar Fascist regime, demonstrating how Fascism had infiltrated everyday life and the difficulties of remembering personal involvement in a Fascist regime. When using oral sources it is important to be aware that silences do not just mean something has been forgotten about. Françoise Zonabend (1984) studied personal memories in a Burgundian village in 1970s. She found that her interviewees did not discuss the Resistance during the Second World War with her. Their silence about the Resistance did not mean it was forgotten, though: it was regularly commemorated at elections. It shows, instead, how informants may not tell observers everything they know or think. The Resistance was a divisive issue in the village, which was not the image of unity that the villagers wanted to create (pp. 196–203).

Subjectivity, Intersubjectivity, and Composure

The fact that oral history builds on people's memories of the past raises the problem of objectivity. According to James Fentress and Chris Wickham (1992), memories are subjective by nature, although they can contain objective facts (p. 7). However, the very subjectivity of oral history is also its advantage. In the words of Portelli (1991), oral sources "tell us not just what people did, but what they wanted to do, what they believed they were doing, what they now think they did…Subjectivity is as much the business of history as the more visible 'facts'" (p. 50). We can use official records, for example, to tell us the date of a marriage or the birth of a child, but not how a bride felt on her wedding day or a mother on the birth of her child. Like any other source, oral history data simply need careful analysis. It is not the case that written documents are reliable and oral sources are not, but there are additional factors when analyzing oral data that need to be taken into account, such as the nature of memory and the relationship between interviewer and interviewee. If done so, oral data can provide an invaluable source of information to the historian.

Indeed, an important issue to bear in mind is the relationship between interviewer and interviewee. While the historian always engages in a relationship with source material, in oral sources they tell the story together. To quote Portelli (1997)

again: "Oral history…refers [to] what the source [the narrator] and the historian [the interviewer] do together at the moment of their encounter in the interview" (p. 3). The historian can influence how and what someone remembers, people can say what they think the interviewer wants to hear and are influenced by the character of the interviewer, and the reverse is also true. People are not just living documents, and there is a special relationship between interviewer and interviewee. This is not necessarily a bad thing: a great advantage of a living source is that you can ask people questions, which you cannot ask documents.

Finally, the narrator often 'performs' his or her identity, and in doing so may engage in a dialogic process where his or her consciousness engages with existing discourses or cultural frameworks: "the self is unstable, performative and draws heavily upon culture" (Abrams, 2010: p. 59). In her aforementioned research on Britain during the Second World War, Penny Summerfield (1998) provided examples of how people draw on public versions of the past as these have been transmitted through a wider, cultural memory (films, photographs, etc.) when constructing their own personal accounts. Drawing on Graham Dawson's concept of 'composure', i.e., the process of "creating accounts of experiences and achieving personal composure, or equilibrium, through constituting oneself as the subject of those stories", she demonstrates how oral history helped her uncover and 'expose' legends for the 'fabrications' that they are (p. 17).

Oral History in Practice: Preparing for the Interview

Before starting an oral history project, it is important to consider costs for traveling; recording equipment and transcription services; potential funding possibilities; and research outputs. Interviewees can be found through local newspapers, residential homes, local history centers and archives, community projects and religious and political organizations (Smith, 2010: p. 22). Snowball sampling, where each respondent gives the name of another person to participate, is a tried and tested means of identifying potential interviewees. According to Katherine Field (2001) snowballing is a particularly appropriate method for finding elderly respondents because it helps secure the trust of interviewees through being 'recommended' to them by their friends (p. 103). However, some awareness of who might be missing from recommendations to interview is useful, as it is likely that snowball sampling will reproduce preexisting networks (Smith, 2010: p. 23).

There are four principal interviewing techniques. First of all, unstructured or in-depth interviewing allows the researcher to gain an understanding of the interviewee's life history. It consists of open-ended questions which allow the interviewee to talk about his or her life in a free-form manner. The life-story approach, as Marie-Françoise Chanfrault-Duchet (1991) has argued, "makes it possible to go beyond the preconstituted discourses and 'surface assertions' collected through survey research. It highlights the complexity, the ambiguities, and even the contradictions of the relations between the subject and the ideological image of woman" (p. 89).

Second, semistructured interviewing combines organized questions with more open-ended questions. It allows for the collection of more specific information on a subject all the while giving the interviewee space to talk freely. Structured interviewing, on the other hand, makes use of a standard set of questions which are ordered in a specific manner, and is most useful when doing quantitative analysis. A focus group or witness seminar, finally, is a collective interviewing technique where a group of people is interviewed all at once. It is a highly suitable technique for gathering a large quantity of information, for example, when doing research on a particular geographical area or a city. It is also useful when investigating issues of collective memory or trauma. At the same time, though, it may pose problems when, for example, interviewees refuse to reveal certain information to one another.

Credibility and Reliability

As with all historical sources, researchers must exercise critical judgment when using interviews – just because someone says something is true does not mean it is true, however convincing they are. Similarly, being a witness to events does not mean the narrator understands the significance of the events they describe. Linda Shopes has therefore advised that the first step in assessing an interview is to consider the credibility of the interviewee and their account. The narrator's relationship to the events under discussion, his or her personal stake in presenting a particular version of events, physical and mental state at the time of the events under discussion and of the interview, as well as the internal consistency of the account all figure into the narrator's reliability. Comparing what the interviewee says both with other respondents and different types of evidence can help establish the accuracy of their account. Does it complement or supplement the other sources, or does it contradict them? If the latter, it is necessary to analyze why this difference occurred. Were interviewees differently situated in relationship to the events under discussion? Might they have different agendas, leading them to tell different versions of the same story? Could the written sources be biased or limited in a particular way? Might intervening events – for example, ideological shifts between the time of the events under discussion and the time of the interview, or subsequent popular cultural accounts of these events – have influenced later memories? Put simply, we need to ask: who is saying what, to whom, for what purpose, and under what circumstances?

The Interviewee: Who Is Talking?

Who a narrator is becomes a cognitive filter for their experiences. In Shopes' words, "What a narrator says, as well as how the narrator says it, is related to his or her social identity (or identities)". Identities are neither singular nor fixed and are defined by both the speaker's relationship to the events under discussion and their temporal distance from them. Feminist historians have shown that women often articulate their life stories around major events in the family life cycle, such as dating events in relation to when their children were born. Women also tend toward "understatement, avoidance of the first person point of view, rare mention of personal accomplishments, and disguised statements of personal power"

(Gwen Etter-Lewis cited in Sangster, 1998: p. 89). In contrast, men are more likely to connect their personal chronologies to public events like wars, elections, and strikes. Ethnicity is also influential. Scott Ellsworth (1982) used the phrase 'segregation of memory' to describe the varying ways blacks and whites remembered the 1921 race riot in Tulsa, Oklahoma (p. 98). Whites recalled either 'very little at all' about members of minority groups or that 'we all got along'. In contrast, blacks offered a less positive and more complex account (pp. 104–107).

The Interviewer: Who Is Asking?

While the interviewee is the central focus of the interview, it is the questions posed by the interviewer that shape the interview's form and content. Smith (2010) recommends a combination of broad questions (i.e., 'Tell me something about…'), precise enquiries (i.e., 'Could you please tell me your date of birth?'), and questions that bring a topic into focus by asking who, what, when questions (p. 27). The interviewer's influence reaches beyond their questioning, though. Linda Shopes explains that the social identities of both the narrator and interviewer are played out in the dynamic of the interview with narrators assessing what they should and should not say to the interviewer. For example, a grandparent being interviewed by a grandchild for a family history project may suppress less savory aspects of the past in an effort to shield the child, serve as a responsible role model, and preserve family myths. Consequently, the interviewer must be aware of what is happening in the interpersonal relationship during the interview situation (Yow, 1994: p. x).

The Interview: What Is Said?

As we have seen, oral history interviews are broad in scope and approach. Shopes reminds us that what is analytically important is the way narrators structure their accounts and the way they select and arrange the elements of what they are saying. As important as what is said is, again, what is not said, i.e., what a narrator misconstrues, ignores, or avoids. Silences can signify many things, though: it can be a simple misunderstanding, a discomfort with a difficult or taboo subject, but it may also reflect mistrust of the interviewer and a cognitive disconnection between interviewer and narrator.

The purposes and outputs of an interview also influence and shape the narrative. For example, community-based oral history projects, which seek to enhance feelings of local identity and pride, often sidestep more difficult and controversial aspects of a community's history. What is said can also be shaped by the intended outcomes of the interview. Narrators whose interviews are intended for web publication, with a potential audience of millions, are perhaps more likely to exercise a greater degree of self-censorship than if their interviews were intended to be placed in an archive.

Finally, the circumstances of the interview also affect what is recalled. Generally, interviews for which both interviewer and interviewee have prepared themselves are likely to be fuller and more detailed accounts than more spontaneous exchanges. Similarly, physical comfort and adequate time help create the expansive mood and unhurried pace that enhances recall. Shopes suggests that the location of the interview subtly influences what a narrator talks about and how they talk about it. Interviews in a person's office, for example, tend to be more formal, less intimate, with the narrator emphasizing public rather than private life. Likewise, an interview with more than one person simultaneously or the presence of a third person in the room where an interview is taking place can constrain a narrator, turning a private exchange into something more akin to a public performance.

Recording and Transcribing Interviews

A good example of how the environment shapes what is said during the interview is when video recording is used instead of audio recording. The advantage of video is that it allows the interviewer (and subsequent users of the recordings) to 'hear' more by seeing body language, facial expressions, and emotions. However, it may prove difficult to manage both interviewing and filming the interviewee, and it is advisable to have someone else handle the camera. As discussed above, the presence of a third person (and indeed the presence of the video camera itself) makes the interview a less private matter. In consequence the interviewee may feel uncomfortable and hold back information. Another side-effect of video interviews is that the narrator might become too attentive to his or her physical appearance or eloquence, to the detriment of the interview itself.

In addition to the choice between audio and video recorder, there are other decisions to be made in respect of recording equipment, with a large range of different types of equipment available in the market. For many researchers, the most convenient audio recorders will be 'solid-state' digital recorders: these usually have a Universal Serial Bus (USB) connection so that the recordings can be easily uploaded to a computer. It is advisable to buy an external microphone – for example a simple tie clip microphone – and headphone for the best sound quality. A unidirectional hand-held microphone or a rifle microphone can be a useful addition if the interview is taking place outdoors.

A good quality recording is important when making transcriptions of interviews, or, at the very least, a summary of the interview detailing the main themes that were discussed, the date, location, and duration of the interview, and some biographical information about the interviewee. A full transcription is a time-consuming matter. While transcription software programs may help, these never transcribe more than 80% of the recording, and it is advisable to hire a professional transcriptionist.

Ethics and Copyright

The interviewee is the copyright holder of the content – i.e., the words – of the interview, which cannot be used unless the interviewee grants his or her 'informed consent'. This will usually be obtained through the interviewee signing a written consent form, although it can be obtained orally on the

recording (which may be more appropriate if the interviewee has low literacy). A consent or clearance form also helps avoid issues with data protection. Whether obtained in writing or orally, the statement of consent will affirm that the interviewee consents to take part in the recording; that they permit you to use it in an agreed way or ways (which need to be specified), for example, as an online publication or to be deposited in an archive; and that they have had the opportunity to specify any restrictions they wish to make. While consent can be obtained after the interview the best time to acquire it is immediately at the end of the interview when both interviewer and interviewee are present to discuss the implications of the statement.

All oral history interviewing requires the researcher to consider a complex range of ethical issues requiring them to balance the need to respect the wishes of the informant whilst also maintaining professional integrity in writing the history which they believe does best justice to all the sources. Some of the most difficult ethics issues relate to oral history interviews involving children, detainees or medical patients, but there are legal and ethical limitations which are applicable to all oral history sources. Some interviewees may have personal issues, for example, a traumatic experience or a disabled child they may not want the researcher to write or talk about in public, or indeed to discuss at all. In such cases it is important to state in advance what kind of information is being collected and how it will be used, so as to enable potential interviewees to decide whether the research project is something they want to participate in.

Archiving and Disseminating Oral History

Oral history that is to be archived needs to comply with a number of requisites: quality and good audio; documentation (i.e., information about interviewee(s), recording dates/venues, etc.); and the presence of signed consent forms. In our current, digital times, many archives also choose to digitize interviews and publish them online. This allows archives to save on transcription costs and make the oral data more easily accessible for researchers located elsewhere. Interviews are also used ever more frequently in museum exhibitions and on museums web sites. As such they manage to enliven the exhibition, increase public support and attract new users or visitors. They also allow visitors to imagine what it was like to live in the past. More importantly, they offer a variety of perspectives on events, thus challenging dominant narratives while giving voice to marginalized groups such as immigrants or women. However, this approach to oral data poses problems, not only in terms of ethics. Making a selection from an interview may not only lead to misinterpretations and wrong impressions, but there is also the risk of error if the digitized interviews are transcribed without the original participants in the interview being able to review the transcript (Ritchie, 2003: p. 176). Finally, there is a danger involved when visitors are exposed to interpretations of ambiguous events, such as genocide and dictatorial regimes, as not all visitors may have the capacity to critically interpret certain perspectives. It is important, then, that the oral data used reflect a wide array of positions and are backed up by historical information or commentary.

Conclusion

If oral history has been growing – as a research method – for several decades now, it was only since the 1980s that it has gained repute and an established position in historical research. Although criticism has not entirely been refuted, for example with regard to the subjective nature of oral history data, nowadays oral history is widely applied both in and outside academia. Researchers intending to partake oral history research should understand the dynamic nature of oral history and its relation to processes of remembering, be aware of (inter)subjective elements involved in interviewing, engage in supplementary and comparative research of written documents, and study the various interviewing techniques and ethical challenges.

Abstract

The subject of *order statistics* deals with the properties and applications of ordered random variables and functions involving them. Let the variates $X_1, \ldots, X_n$ be arranged in ascending order and written $X_{1:n} \leq \cdots \leq X_{r:n} \leq \cdots \leq X_{n:n}$ Then $X_{r:n}$ is the rth order statistic, $X_{1:n}$ and $X_{n:n}$ are the extremes, and $X_{(n+1)/2:n}$ is the median for n odd. Important functions of order statistics include the range $W_n = X_{n:n} - X_{1:n}$, the *trimmed means* $(X_{r+1:n} + X_{r+2:n} + \cdots + X_{n-r:n})/(n-2r)$, $1 \leq r < n/2$, and the L-statistics $c_{1n}X_{1:n} + \cdots + c_{nn}X_{n:n}$. Both finite-sample and asymptotic theory are outlined. Major applications of order statistics include: (1) the estimation of location and scale parameters; (2) the analysis of data where the smallest r_1 and/or the largest r_2 observations have been 'censored'; (3) the treatment of outliers; (4) robust estimation; (5) selection procedures; (6) data compression; and (7) probability plotting. If the bivariate sample $(X_1, Y_1), \ldots, (X_n, Y_n)$ is ordered by the Xs, then the Y-variate paired with $X_{r:n}$ is called the concomitant of the rth order statistic. Some uses of these concomitants are also noted.

The field of *order statistics* deals with the properties and applications of ordered random variables and of functions involving them. Simple examples, useful as descriptive statistics, are the sample maximum and minimum, median, range, and trimmed means. Major applications include the estimation of location and scale parameters in complete or censored samples, selection procedures, the treatment of outliers, robust estimation, simultaneous inference, data compression, and probability plotting. Although important in the theory of nonparametric statistics, the subject of order statistics is very largely parametric, that is, its results depend generally on the form of the population(s) sampled.

Introduction

Let the variates $X_1, \ldots, X_n$ be arranged in ascending order and written $X_{1:n} \leq \cdots \leq X_{r:n} \leq \cdots \leq X_{n:n}$. Then $X_{r:n}$ is the rth order statistic ($r = 1, \ldots, n$), a term also applied to the corresponding observed value, $x_{r:n}$. The *median* is $X_{(n+1)/2:n}$ for n odd and $\frac{1}{2}(X_{n/2:n} + X_{n/2+1:n})$ for n even. Helped by their simplicity, the median and the *range*, $X_{n:n} - X_{1:n}$, have long been valuable as measures of location and scale, respectively.

Consider the following illustrative data, with $i = 1, \ldots, 8$

x_i :	16	40	23	12	240	33	17	27
$x_{i:8}$:	12	16	17	23	27	33	40	240

These figures may represent the annual incomes (in multiples of \$1000) at age 30 of eight high-school dropouts. Because of the *outlier* $x_5 = 240$, the median, $\frac{1}{2}(23 + 27) = 25$, clearly gives a better picture of the group than the mean, 51. The median would in fact be unchanged as long as $x_5 \geq 27$, which shows just how *robust* the median is.

Next, suppose that the x_i are test scores out of a total of 40. If we are unable to correct the impossible score of 240, we eliminate or *censor* it. The median is then $x_{4:7} = 23$, no longer very different from the mean, $\bar{x} = 24$. The range is not robust, dropping from 228 to 28, and is therefore useful in detecting outliers, which are seldom as obvious as in the above data (see Section Outliers and Selection of the Best). For 'well-behaved' data, the range provides a simple measure of variability or scale.

In time series, $X_1, X_2, \ldots$, these descriptive statistics are particularly helpful when based on small moving subsamples $X_j, X_{j+1}, \ldots, X_{j+n-1}$ ($j = 1, 2, \ldots$). The resulting *moving* (or *running*) *medians* provide a current measure of location that, unlike the moving mean, is not too sensitive to outliers. The sequence of moving medians represents a smoothing of the data, with important applications in signal and image processing. Moving ranges are useful in quality control charts, where their sensitivity to outliers is a desirable feature. If more robust current estimators of dispersion are required, one can turn to the difference of the second largest and the second smallest in each moving sample, etc.

Again, the above x_i may represent response times to a stimulus. The *extremes*, 12 and 240, are then of particular interest (see Section Extreme Order Statistics). Of course, we would want more extensive data for which we may also wish to study the *upper* and *lower records*, here (16, 40, 240) and (16, 12) (*see* Nonparametric Statistics: Records).

Basic Distribution Theory

If $X_1, \ldots, X_n$ is a random sample from a population with cumulative distribution function (cdf) $F(x)$, then the cdf of $X_{r:n}$ is given by

$$F_{X_{r:n}}(x) = P(X_{r:n} \leq x) = P$$

(at least r of $X_1, \ldots, X_n$ are less than or equal to x)

$$= \sum_{i=r}^{n} \binom{n}{i} F^i(x)[1 - F(x)]^{n-i} \qquad [1]$$

since the term in the summand is the binomial probability that exactly i of $X_1, \ldots, X_n$ are less than or equal to x.

In handling order statistics, usually it is assumed that the underlying variate X is continuous. Note that this assumption is not needed in the derivation of eqn [1]. Also, if X can take only integral values, then $P(X_{r:n}=x)=F_{xr:n}(x)-F_{xr:n}(x-1)$. However, if X is discrete, the probability of ties among the observations is positive, which tends to complicate the distribution theory (see, e.g., David, 1981: p. 13, Arnold et al., 1992: p. 41).

If the probability density function (pdf) $f(x)$ exists, as we will assume from here on, then differentiation of eqn [1] yields

$$f_{X_{r:n}}(x) = \frac{n!}{(r-1)!(n-r)!}F^{r-1}(x)f(x)[1-F(x)]^{n-r} \qquad [2]$$

Also, the joint pdf of $X_{r:n}$ and $X_{s:n}$ $(1 \le r < s \le n)$ is, for $x \le y$ (e.g., David, 1981: p. 10; Arnold et al., 1992: p. 16)

$$f_{X_{r:n}X_{s:n}}(x,y) = \frac{n!}{(r-1)!(s-r-1)!(r-s)!} \times F^{r-1}(x)f(x)[F(y)-F(x)]^{s-r-1}f(y)[1-F(y)]^{n-s} \qquad [3]$$

Equations [2] and [3] are fundamental and permit the calculation, usually by numerical integration, of the means, variances, and covariances. Also, eqn [3] makes possible the derivation, by standard methods, of the pdf of functions of two order statistics, such as the range $W_n = X_{n:n} - X_{1:n}$. To facilitate the use of order statistics, extensive tables have been developed, especially when $F(x)=\Phi(x)$, the standard normal cdf (see Pearson and Hartley, 1970/1972; Harter and Balakrishnan, 1996, 1997).

Distribution-Free Interval Estimation

Three important types of distribution-free intervals involving order statistics may be distinguished. For simplicity we assume that $F(x)$ is strictly increasing for $0 < F(x) < 1$.

Confidence Intervals for Quantiles

The (population) quantile of order p, ξ_p, is defined by $F(\xi_p)=p$, $0<p<1$. In particular, $\xi_{1/2}$ is the median. Since, for $r<s$ $P(X_{r:n}<\xi_p<X_{s:n}) = P(X_{r:n}<\xi_p) - P(X_{s:n}<\xi_p)$, it follows from eqn [1] that the interval $(X_{r:n}, X_{s:n})$ covers ξ_p with probability

$$P_1 = \sum_{i=r}^{s-1}\binom{n}{i}p^i(1-p)^{n-i}$$

Tolerance Intervals

The focus here is on the probability, P_2, with which $(X_{r:n}, X_{s:n})$ covers a proportion γ of the underlying population. Thus $P_2 = P\{F(X_{s:n}) - F(X_{r:n}) \ge \gamma\}$ Since $F(x)$ is a uniform (0, 1) variate, U, $P_2 = P\ (U_{s:n} - U_{r:n} \ge \gamma) = 1 - I_\gamma(s-r,\ n-s\ +r+1)$, with the help of eqn [3], where $I_\gamma\ (a, b)$ is the incomplete beta function.

Prediction Intervals

Let $X_1, \ldots, X_m, Y_1, \ldots, Y_n$ be independent variates with cdf $F(x)$. The Xs may represent current observations and the Ys future observations. What is the probability, P_3, that $Y_{t:n}$ $(t=1, \ldots, n)$ falls between $X_{r:m}$ and $X_{s:m}$ $(1 \le r < s \le m)$? It can be shown that $P_3 = P(Y_{t:n} > X_{r:m}) - P(Y_{t:n} > X_{s:m})$, where

$$P(Y_{t:n} > X_{r:n}) = \sum_{i \ge r}\binom{m}{i}\binom{n}{r+t-1-i}\Big/\binom{m+n}{r+t-1}$$

A good account from the user's point of view of all these intervals is given in Chapter 5 of Hahn and Meeker (1991).

Estimation of Parameters

An important simple example is the use of range in quality control to estimate the standard deviation (sd) σ in a normal sample. If $w_{n;\alpha}$ denotes the upper α significance point of the range in a standard normal population, then from $P(w_{n;1-a/2} < W_n/\sigma < w_{n;a/2}) = 1-\alpha$ it follows that a $(1-\alpha)$ confidence interval (CI) for σ is

$$\frac{w_n}{w_{n;\alpha/2}} < \sigma < \frac{w_n}{w_{n:1-\alpha/2}}$$

where w_n is the observed value of the range.

An unbiased point estimator of σ is $\widehat{\sigma}_W = W_n/d_{n,}$, where $d_n = E(W_n/\sigma)$ is widely tabulated. Let $\widehat{\sigma}_s$ denote the unbiased root-mean-square estimator of σ. In small samples the efficiency of $\widehat{\sigma}_W$, i.e., var $\widehat{\sigma}_s$/var $\widehat{\sigma}_W$, is quite high (0.955 for $n=5$).

More systematically, linear functions of the order statistics (L-statistics) can be used to estimate both location and scale parameters, μ and σ (not necessarily mean and sd), for distributions with pdf of the form

$$f(x;\mu,\sigma) = \frac{1}{\sigma}g\left(\frac{x-\mu}{\sigma}\right), \quad \sigma > 0 \qquad [4]$$

With $Y=(X-\mu)/\sigma$, let $\alpha_{r:n} = E\ (Y_{r:n})$ and $\beta_{rs:n} = \text{cov}\ (Y_{r:n},\ Y_{s:n})$ $(r,\ s=1,\ \ldots,\ n)$. It follows that $X_{r:n} = \mu + \sigma Y_{r:n}$, so that

$$E(X_{r:n}) = \mu + \sigma\alpha_{r:n} \qquad [5]$$

$$\text{cov}(X_{r:n}, X_{s:n}) = \sigma^2\beta_{rs:n} \qquad [6]$$

A major advance was made by Lloyd (1952), who recognized that the generalized Gauss–Markov theorem can be applied to the estimation of μ and σ, in view of eqns [5] and [6]. This yields the best linear unbiased estimators (BLUEs).

$$\mu^* = \sum_{i=1}^{n} a_{in}X_{i:n} \text{ and } \sigma^* = \sum_{i-1}^{n} b_{in}X_{i:n} \qquad [7]$$

where the a_{in} and b_{in} are functions of the $\alpha_{i:n}$ and $\beta_{ij:n}$ and can be evaluated once and for all. For tables in the normal case, see Sarhan and Greenberg (1962).

The statistics in eqn in [7] provide estimators that are unbiased and of minimum variance within the class of linear unbiased estimators. They are particularly convenient for data in which some of the smallest and/or largest observations have been censored, since maximum likelihood (ML) estimation tends to be difficult in this situation. Also, for complete and censored samples, ML estimation may produce biased estimators. However, μ^* and σ^* may not have the smallest mean

squared error, even among L-statistics. Simplified approximate estimation procedures are also possible (see, e.g., David, 1981: p. 128 or Arnold et al., 1992: p. 171).

Asymptotic Theory

Except for the distribution-free results of Section Basic Distribution Theory, the practical use of order statistics in finite samples depends heavily on the availability of tables or computer programs appropriate for the underlying population. In large samples, asymptotic theory can provide approximate results that are both simpler and more widely applicable.

It is useful to distinguish three situations as $n \to \infty$: (1) *Central order statistics* $X_{(np):n}$, where (np) denotes here the largest integer $\leq np+1$, with $0<p<1$; (2) *Extreme order statistics* $X_{r:n}$, where $r=1, \ldots, m$ or $r=n-m+1, \ldots n$, and m is a fixed positive integer; (3) *Intermediate order statistics* $X_{r:n}$ or $X_{n-r+1:n}$, where $r \to \infty$ but $r/n \to 0$.

Central Order Statistics

Corresponding to the population quantile ξ_p of Section 2.1, it is natural to call $X_{(np):n}$ a *sample quantile*. The following important result then holds (e.g., David, 1981: p. 254). Let $X_1, \ldots, X_n$ be a random sample from a population with pdf $f(x)$ and put $n_j=(np_j)$, $j=1, \ldots, k$, where k is fixed and $0<p_1<p_2<\cdots<p_k<1$. If $0<p(\xi_{pj})<\infty$, $j=1, \ldots, k$, then the asymptotic joint distribution of $\sqrt{n}(X_{n_1:n}-\xi_{p_1}), \ldots, \sqrt{n}(X_{n_k:n}-\xi_{p_k})$ is k-dimensional normal, with zero mean vector and covariance matrix $(\sigma_{jj'})$, where

$$(\sigma_{jj'}) = \frac{p_j(1-p_j)}{f\left(\xi_{p_j}\right)f\left(\xi_{p_j}\right)} j \leq j'$$

As a very special case, it follows that for the median $M_n=X_{(n+1)/2:n}$ (n odd), as $n \to \infty$, $\sqrt{n}(M_n-\mu) \to N(0, \pi\sigma^2/2)$ showing incidentally that, as an estimator of μ, M_n has asymptotic efficiency (relative to $\overline{X}$) of $2/\pi=0.637$. The same result holds for n even.

Extreme Order Statistics

The situation is more complicated when $p_1=0$ or $p_k=1$, corresponding to the *extremes* $X_{1:n}$, $X_{n:n}$ and more generally to the mth extremes $X_{m:n}$, $X_{n+1-m:n}$, where m is a fixed positive integer. For $X_{n:n}$, suitably normalized, there are three limiting distributions, the simplest of which is the Type III extreme-value distribution with cdf $\Lambda_3(x)=\exp(-e^{-x})$ $-\infty<x<\infty$. This distribution has been found very useful in describing the behavior of floods and other extreme meteorological phenomena. A convenient sufficient condition for $\Lambda_3(x)$ to be the appropriate limiting distribution is that the underlying distribution satisfy

$$\lim_{x\to\infty} \frac{d}{dx}\left[\frac{1-F(x)}{f(x)}\right] = 0 \qquad [8]$$

Then

$$\lim_{x\to\infty} P\{(X_{n:n}-a_n)nf(a_n) \leq x = \Lambda_3(x)$$

where a_n is given by $F(a_n)=1-1/n$. Distributions for which eqn [8] holds include the normal, gamma, and logistic families. For a full treatment of the extreme-value case, see Galambos (1987).

Intermediate Order Statistics

An example of an intermediate order statistic is $X_{\sqrt{n}:n}$. A suitably normalized form of $X_{r:n}$ may have either a normal or nonnormal asymptotic distribution (e.g., Arnold et al., 1992: p. 226).

Asymptotic Independence Results

A useful result is that, after appropriate normalization, upper extremes are asymptotically independent of lower extremes. Moreover, all extremes are asymptotically independent of the sample mean (e.g., David, 1981: pp. 267–270).

L-Statistics

It is clear from the above that a linear function of sample quantiles, $\sum_{j=1}^{k} c_j X_{nj:n}$, tends to normality as $n \to \infty$ (k fixed). On the other hand, the asymptotic distribution of linear functions of the extremes, such as the range, will be more complicated. An L-statistic, $\sum_{j=1}^{k} c_{in} X_{i:n}$, involving extreme, intermediate, and central order statistics, may be asymptotically normal or nonnormal, depending on the underlying distribution and on how much weight is placed on the extreme order statistics.

Applications

Probability Plotting

This very useful graphical method typically is applied to data assumed to follow a distribution depending, as in eqn [3], only on location and scale parameters μ and σ. The ordered observations $x_{i:n}(i=1, \ldots, n)$ are plotted against $\nu_i=G^{-1}(p_i)$, where G is the cdf of $Y=(X-\mu)/\sigma$ and the p_i are probability levels, such as $p_i=(i-1/2)/n$. The plotting is immediate if probability paper corresponding to G is available, as it is for, for example, the normal, lognormal, and Weibull distributions. If a straight-line fit through the points $(\nu_i, x_{i:n})$ seems unreasonable, doubt is cast on the appropriateness of G. Often this simple procedure is adequate, but it may be followed up by a more formal test of goodness-of-fit.

If a straight line fits satisfactorily, a second use may be made of the graph: σ may be estimated by the slope of the line and μ by its intercept on the vertical axis. A detailed account of probability plotting and the related *hazard plotting* is given in Nelson (1982).

Selection Differentials and Concomitants of Order Statistics

If the top k ($<n$) individuals are chosen in a sample from a population with mean μ and sd σ, then $D_{k,n}=(X_{n-k+1:n}+\cdots+X_{n:n}-k\mu)/k\sigma$ measures the superiority, in sd units, of the selected group. The mean and variance of this *selection differential* is given immediately by eqns [5] and

[6] as $E\ (D_{k,n}) = \sum \alpha_{i:n}/k$, var $(D_{k,n}) = \sum\sum \beta_{ij:n}/k^2$, where all summations run from $n-k+1$ to n.

Often one is interested in how this group performs on some related measurement Y. Thus, X may refer to a screening test and Y to a later test or X to a parent animal and Y to an offspring. The Y-variate paired with $X_{r:n}$ may be denoted by $Y_{[r:n]}$ and called the *concomitant of the rth order statistic*. Corresponding to $D_{k,n}$, the superiority of the selected group on the Y-measurement is, with obvious notation, $D_{[k,n]} = (\sum Y_{[i:n]} - k\mu_Y)/k\sigma_Y$. If Y is linearly related to X, such that $Y_i = \mu_Y + \rho\sigma_Y(X_i - \mu_x)/\sigma_x + Z_i$ where ρ is the correlation coefficient between X and Y, and Z_i is independent of X_i, with mean 0 and variance $\sigma_Y^2(1-p^2)$, then $Y_{[r:n]} = \mu_Y + \rho\sigma_Y(X_{r:n} - \mu_x)/\sigma_x + Z_{[r]}$ where $Z_{[r]}$ is the Z-variate associated with $X_{r:n}$ (e.g., David, 1981: p. 110). It follows that $EY_{r:n} = \mu_Y + \rho\sigma_Y\alpha_{r:n}$, $\mathrm{var}Y_{[r:n]} = \sigma_Y^2(p^2\beta_{rr:n} + 1 - p^2)$, $\mathrm{cov}(Y_{[r:n]}, Y_{[s:n]}) = p^2\sigma_Y^2\beta_{rs:n} r \neq s$ so that the mean and variance of $D_{[k,n]}$, the *induced selection differential*, are $ED_{[k,n]} = \rho ED_{k:n}$, var $D_{[k,n]} = \rho^2 \mathrm{var}\ D_{k:n} + (1-\rho^2)/k$. The asymptotic distribution of $D_{[k:n]}$ as well as many other properties and applications of concomitants of order statistics are treated in David and Nagaraja (1998).

Outliers and Selection of the Best

Order statistics, especially $X_{n:n}$ and $X_{1:n}$, enter naturally into many outlier tests. Thus, if $X_1, \ldots, X_n$ are supposedly a random sample from a normal distribution with unknown mean and known variance σ^2, then large values of $B_n = (X_{n:n} - \overline{X})/\sigma$ make this null hypothesis, H_0, suspect. The corresponding two-sided statistic is $B'_n = \max_{i=1,\ldots,n} \left| X_i - \overline{X}\right)/\sigma$. If σ is unknown, studentized versions of B_n or B'_n can be used. The subject, with its many ramifications, is treated extensively in Barnett and Lewis (1994), where tables needed to carry out such tests are given. If the observed value of the chosen statistic is large enough, H_0 is rejected and $X_{n:n}$ (or $X_{1:n}$) becomes a candidate for further examination or rejection.

The foregoing approach is related closely to the following multiple decision procedure, illustrated on the balanced one-way classification with n 'treatment' means $\overline{X}_i$, $i = 1, \ldots, n$, each based on m replications. To test the null hypothesis H_0 of equal population means $\mu_1, \ldots, \mu_n$ against the 'slippage' alternative $\mu_1 = \cdots = \mu_{i-1} = \mu_{i+1} = \cdots \mu_n$ and $\mu_i = \mu_1 + \Delta$, where i and $\Delta < 0$ are unknown, $n+1$ decisions may be taken, that is, D_0:H_0 holds or D_i: the ith treatment mean has slipped to the right. Under the usual normal-theory assumptions, an optimal procedure at significance level α is to choose D_M if (e.g., David, 1981: p. 226) $C_{n,\nu} = m(\overline{X}_M - \overline{X})/(\mathrm{TSS})^{1/2} > c_n, \nu : \alpha$, where M is the subscript corresponding to the largest $\overline{X}_i$, TSS is the analysis of variance total sum of squares, and $c_{n,\nu:\alpha}$, with $\nu = n(m-1)$, is given in Table 26a of Pearson and Hartley (1970/1972). If $C_{n,\upsilon} < c_{n,\upsilon:\alpha}$ the decision D_0 is taken. Slippage in either direction can be handled similarly with Table 26b.

In the above, the focus is on the detection of a single outlier or a single superior (or inferior) treatment. The handling of multiple outliers is an important part of Barnett and Lewis (1994) (*see* Statistical Analysis, Special Problems of: Outliers).

Simultaneous Inference

Order statistics play an important supporting role in simultaneous inference procedures. A well-known example is Tukey's use of the studentized range in setting simultaneous confidence intervals for the treatment means in fixed-effects balanced designs (e.g., *see* Hypothesis Tests, Multiplicity of).

Robust Estimation

Here one gives up the classical idea of using an estimator that is optimal under tightly specified conditions in favor of an estimator that retains reasonably good properties under a variety of departures from the hypothesized situation. Since the largest and smallest observations tend to be more influenced by such departures, which include the presence of outliers, many robust procedures are based on the more central order statistics. A simple example is provided by the *trimmed means*

$$T_n(j) = \sum_{i=j+1}^{n-j} \frac{X_{i:n}}{n-2j} \quad 0 < j < \frac{1}{2}n$$

which include the sample median as a special case. For a very readable treatment of robust methods see Hoaglin et al. (1983) (see also Robustness in Statistics).

Data Compression and Optimal Spacing

Given a large random sample of size n from a population with pdf, eqn [4], it is possible to estimate μ or σ or both from a fixed small number k of well chosen order statistics. The loss in efficiency of estimation may be more than compensated by the storage space gained, especially as a test of the assumed underlying distribution can still be made by probability plotting. For example, in the case of a normal population, the optimal estimator of μ is, for $k = 4$,

$$\mu^* = 0.1918\left(X_{(0.1068n):n} + X_{(0.8932n):n}\right) + 0.3082\left(X_{(0.3512nn):n} + X_{(0.6488n):n}\right)$$

where $(0.1068n)$ is the largest integer $\leq 0.1068n + 1$, etc. The estimator μ^* has asymptotic efficiency (AE) 0.920 and, since it does not involve the more extreme order statistics, is more robust than$\overline{X}$. Also, μ^* is much more efficient than the median (AE = 0.637) (see, e.g., David, 1981: Section 7.6).

Concluding Remarks

The two large multiauthored volumes (Balakrishnan and Rao, 1998a,b) cover many more topics in both theory and applications of order statistics than can even be mentioned here. Additional applications include *ranked set sampling* and especially the use of *median, order-statistic*, and other *filters* in signal and image processing.

Abstract

The concepts of a relation, a mapping, and an operation are introduced. An ordered relational structure consists of a set and a few relations defined on it. The formal definition is presented and illustrated by numerous examples from social sciences and from mathematics. Homomorphisms and isomorphisms between structures are defined. These are mappings of one structure into another which, in a way, keep its structural properties, while possibly changing the meaning of its primitives. Automorphisms are mappings of the structure onto itself. They reveal most of its important properties. The group of automorphisms of a structure is described leading to the concept of homogeneity and uniqueness of a structure. The Alper/Narens theorem characterizes structures on the reals with specified homogeneity and uniqueness properties of their automorphism group. This famous theorem is discussed along with a recent generalization. The order topology and some results in connection with it are presented. Finally, the problems which arise when a structure is embedded into a Dedekind complete ordered relational structure, are briefly mentioned. This article is closely related to the article on representational measurement theory. Furthermore, the section on the completion of structures draws on Section Order Topology of the article Partial Orders.

Ordered relational structures are the working place for representational measurement theory. If one thinks of measurement theory as a kind of interface between empirically observed phenomena and abstract structures which one can work on mathematically, a common language for both is needed. In this context the objects under scrutiny are just elements of a set and the observed interrelations (at least those which are deemed relevant by some scientific question) are modeled as abstract relations between these elements. In the investigation of such structures nobody is interested in the actual meaning attached to the object and their relations. This approach is to some extent similar to the development of geometry, where one works on points, lines, planes, etc., without ever defining these concepts. The only thing provided is a set of axioms which these objects satisfy. (*see* Axiomatic Theories for a deeper description of this approach.) Furthermore, the theory must take care of the process of mapping one structure into another while keeping its essential features intact.

Many of the phenomena for which one needs measurements exhibit some kind of dominance, preference, or ordering. Therefore, most of the relational structures which are used in measurement theory carry some kind of abstract ordering relation (linear, weak, or partial orders).

In short, an 'ordered relational structure' consists of a baseset, here always denoted by A, an order relation on A, and possibly further relations on A. It is the foundation on which representational measurement theory is built. Sometimes A is the Cartesian product of other sets, sometimes it is the union of disjoint sets and some of the relations are between these sets (see Section Relations, Functions, Operations for definitions). While the investigation of one such structure may be a part of mathematics, in applications in the behavioral and social sciences the common frame consists of at least two relational structures, one to describe in a qualitative way the investigated part of reality and the other a formal, mathematical, or numerical structure that is well understood or that can be investigated by means of mathematics, logic, or computation. Such a development can yield results relevant to the empirical subject under scrutiny if the investigator succeeds in faithfully mapping the qualitative structure into the formal structure.

The requirements for this process, i.e., building useful structures and mapping them 'faithfully' into one another are discussed in the sequel and in the article Measurement, Representational Theory of.

Relations, Functions, Operations

Let A and B be two sets. The 'Cartesian product' of these sets is denoted by $A \times B$ and consists of all ordered pairs (a, b) with $a \in A$ and $b \in B$. Any subset $R \subseteq A \times B$ is called a 'binary relation' between A and B. The case $A = B$ is of particular interest; in this situation R is called a 'relation' on A. Clearly, this construction can easily be generalized to a k-ary relation, denoting a subset of the Cartesian product of k sets, i.e., $R \subseteq A_1 \times A_2 \times \ldots \times A_k$. If in this case all sets A_i equal A, then the Cartesian product is denoted as A^k and R is a k-ary relation on A. This broad concept is often used to describe parts of mathematics, mostly with further restrictions and properties on R, but it is also possible to use it in everyday situations. For example, let A be a set of persons and let $(a, b) \in R$ denote the fact that a and b have the same birthday. Or if A is the set of participants in a tournament and $(a, b) \in R$ denotes the result 'a beats b,' then R is an encoding of the outcome of this tournament.

We now classify the possible relations. Among the 'binary relations' there is the prominent class of 'order relations' (*see* Partial Orders for definitions). In this article we only consider weak and linear orders, denoted by $\precsim$. A 'weak order' satisfies by definition 'transitivity,' i.e., $a \precsim b$ and $b \precsim c$ implies $a \precsim c$, and 'completeness,' i.e., for all $a, b \in A$ holds $a \precsim b$ or $b \precsim a$. A

'linear order' is a weak order satisfying 'antisymmetry,' i.e., for all $a, b \in A$ holds, if $a \precsim b$ and $b \precsim a$ then $a = b$.

Now we are ready to define an 'ordered relational structure.' It consists of a nonempty set A, a weak order $\precsim$ on A, and possibly more relations R_i with $i \in I$ for some index set I. In the sequel an ordered relational structure is denoted by

$$\mathscr{A} = (A, \precsim, R_i, i \in I)$$

If R_i is a k_i-ary relation, then $(k_i, i \in I)$ is the *type* of the structure.

Closely related to order relations are 'equivalence relations.' Such a relation $\sim$ satisfies by definition 'reflexivity,' i.e., $a \sim a$, 'symmetry' i.e., $a \sim b$ implies $b \sim a$, and transitivity. A set on which an equivalence relation is defined can be partitioned into disjoint subsets of equivalent elements. These subsets are called 'equivalence classes.' Often one can reduce a structure by replacing the base set A with the set of its equivalence classes.

There are a few operations on relations that can be employed to generate new relations. We define them only for binary relations on a set A. Thus, in what follows $R, S \subseteq A \times A$.

$$R^*: = \{(b, a); (a, b) \in R\}$$

$$R \circ S: = \{(a, b); \exists c \in A (a, c) \in R, (c, b) \in S\}$$

$$R^2: = R \circ R$$

$$R^n: = R \circ R^{n-1}$$

Thus, if $(a, b) \in R$ means 'a beats b in a tournament' then $(a, b) \in R^*$ means 'a is beaten by b,' and aR^2b means 'a has beaten someone who in turn has beaten b.'

Mappings between two sets A, B are a particular kind of binary relation. A relation f between A and B is a 'mapping' (*or* 'function),' when, for all $a \in A$ there is exactly one $b \in B$ such that $(a, b) \in f$. In this case one writes $f(a) = b$ rather then $(a, b) \in f$. The comprehensive notation is

$$f: A \to B, \quad a \mapsto b = f(a)$$

A is called the 'domain' and B the 'range' of f. If $b = f(a)$ then b is the image of a (under f) and a is a preimage of b (there may be more than one). For a subset A' of A the set of images of all $a \in A'$ is denoted by $f(A')$. In particular $f(A) = \{b \in B;$ there is an $a \in A$ such that $f(a) = b\}$. A mapping is 'surjective' if $f(A) = B$ and 'injective' if $f(a_1) = f(a_2)$ implies $a_1 = a_2$. Thus, an injective function allows at most one preimage of each element in its domain. An injective and surjective function is called 'bijective' or a 'bijection.' Bijective functions can be 'inverted;' this concept denotes the function $f^{-1}: B \to A$ such that $f^{-1}(b) = a$ if $f(a) = b$.

Sometimes bijections $f: A \to A$ are called 'permutations.' For instance, when dealing with finite sets this terminology is quite usual. Under these bijections there is one which is particularly simple, the identity mapping, denoted by id_A. It is defined by $\mathrm{id}_A: A \to A$ and $\mathrm{id}_A(a) = a$ for all $a \in A$.

Functions can be 'concatenated,' i.e., if $f: A \to B$ and $g: f(A) \to C$ then $g \circ f: A \to C$ by setting $g \circ f(a) := g(f(a))$. Note that the order of f, g in $g \circ f$ is important – $f \circ g$ is not always defined and if it is, e.g., if $A = f(A) = C$, then in general $f \circ g \neq g \circ f$. One has $f \circ \mathrm{id}_A = f$ and $\mathrm{id}_{f(A)} \circ f = f$. If f is bijective then $f^{-1} \circ f = \mathrm{id}_A$ and $f \circ f^{-1} = \mathrm{id}_B$.

If the respective conditions on the domains and ranges are met then the $\circ$-operation of functions is 'associative,' i.e., $h \circ (g \circ f) = (h \circ g) \circ f$. Thus, the brackets can be omitted, and we simply write $h \circ g \circ f$.

Mathematical operations such as addition of real numbers are special functions. A '(binary) operation' $\bullet$ on A is a function.

$$\bullet: A \times A \to A \quad (a, b) \mapsto a \bullet b$$

Thus, it is a special kind of ternary (i.e., 3-ary) relation. It is a 'partial' operation if its domain is a proper subset of $A \times A$. Examples of structures with operations frequently occur in measurement theory under the name 'extensive' or 'positive concatenation' structures (*see* Measurement, Representational Theory of).

An operation is 'associative' if $a \bullet (b \bullet c) = (a \bullet b) \bullet c$. Sometimes the notion of 'weak associativity' is needed. If $a \backsim b$ denotes $a \precsim b$ and $b \precsim a$ then the operation $\bullet$ is weakly associative if $a \bullet (b \bullet c) \sim (a \bullet b) \bullet c$. As already mentioned, weak association might arise in a structure $(A, \precsim, \bullet)$, where $\precsim$ is a weak order.

It should be noted in passing that the relation $\sim$ defined in the previous paragraph is an equivalence relation. It is often used if one wants to replace a given weak order by a linear order (*see* Partial Orders).

Examples of Ordered Relational Structures

Weights

Consider a collection of weights and let $a \precsim b$ stand for: If a is put in one pan of a balance and b in the other, then the one containing b remains in place or deflects the pointer to b's side. Let $a \bullet b$ denote putting a and b in one pan. Let A denote the set of all weights and of all combinations that can be formed by putting two or more of the weights in one pan. It can be assumed, with reasonable accuracy that $(A, \precsim, \bullet)$ is an ordered relational structure. Furthermore, the operation $\bullet$ will be approximately weakly associative and positive, i.e., $a \prec a \bullet b$ for all $b \in A$ ($x \prec y$ is short for $x \precsim y$ and not $y \precsim x$). Still more, it will satisfy 'commutativity' $a \bullet b = b \bullet a$.

Guttman Scaling

Let A be a set of testees and B a set of items to be solved by each $a \in A$. For $a \in A$ and $b \in B$ let aRb denote that person a fails to solve item b correctly. Now assume that the relation R (which is between A and B) satisfies

$$aRb, \ a'Rb, \ \text{not } a'Rb' \quad \text{implies} \quad aRb'$$

The system (A, B, R) is not an ordered relational structure in the sense of the previous section because R, being a biorder (*see* Partial Orders), is not a weak order on one of the sets A, B. However, we can easily construct an ordered relational structure from it. Let $C := A \cup B$ and on C define: for $a, a' \in A$ $a \precsim a'$ if person a' solves at least as many items as does person a, and for $b, b' \in B$ define $b \precsim b'$ if b' is solved by at most as many

persons as b. Finally define $a \precsim b$ if aRb, and $b \precsim a$ if not aRb. Then it can be shown that $\precsim$ is a weak order on C; thus, $(C, \precsim)$ is an ordered relational structure.

Several Orders on One Set

Let S be a collection of different societies. Assume they can be weakly ordered with respect to social mobilization (relation K) and social frustration (relation L) of its members, and also with respect to economic development (relation M).

This is a case of a structure $\mathscr{A} := (A, K, L, M)$ where K, L, M are all weak orders on A. Let the weak orders satisfy the following compatibility relations: For all $a, b \in A$

$$\text{if } aKb, bLa \quad \text{then } aMb \qquad [1]$$

$$\text{if } aKb, bMa \quad \text{then } aLb \qquad [2]$$

$$\text{if } aLb, aMb \quad \text{then } aKb \qquad [3]$$

Suck (1990) has shown that such a structure can be transformed to an ordered relational structure on a Cartesian product which turns out to be a conjoint measurement structure satisfying independence (*see* Measurement Theory: Conjoint). As an application of such a structure Suck and Getta (1994) gave an axiomatization and representation of Coombs's portfolio theory in which A is a set of gambles (wins and losses with certain probabilities), K is an ordering of these gambles according to preference to play such gambles by subjects, L is an ordering by expected value, and M is an ordering by perceived riskiness of the gambles. The possibility to associate this situation with conjoint measurement proved very helpful in analyzing the structure and data.

Wille and Wille (1993) considered similar relational structures. They investigated the possibility of homomorphically mapping a structure satisfying eqns. [1–3] into the reals without the detour via conjoint measurement. They related their investigation to the 'Huntington controversy' arising from Huntington (1968) who presented 'equations' such as:

$$\frac{\text{Social mobilization}}{\text{Economic development}} = \text{Social frustration} \qquad [4]$$

This use of 'equations' was severely criticized, mainly with the argument that the variables of the equation are not measurable entities (*see* Mathematical Psychology). Formulating the structure in the above way can provide the means to solve this controversy. Either applying conjoint measurement in the sense of Suck (1990) or the results of Wille and Wille (1993) would yield a framework in which a decision on the validity of eqn. [4] is possible.

Homomorphisms, Isomorphisms

It is often useful and even necessary to consider several relational structures at the same time. In this case it is important to describe how similar these structures are, and how one can go from one structure to the next or – more intuitively – how one can transfer knowledge from one structure to another. Examples of this technique occur in measurement theory where usually one structure has as its base set (a subset of) the reals, or more generally, when there is one structure which is thoroughly investigated and all or many of its properties are well known. In such cases it is without doubt helpful to compare such a structure to the one under empirical investigation and to point out the manner in which the two structures resemble each other.

Let $\mathscr{A} = (A, R_i, i \in I)$ and $\mathscr{B} = (B, S_j, j \in J)$ be two relational structures. Then a mapping $\varphi: A \to B$ is called a 'homomorphism' between $\mathscr{A}$ and $\mathscr{B}$ if the structures are of the same type $(k_i, i \in I)$ and for all $i \in I$ and for all $(a_1, \ldots, a_k k_i) \in A^{ki}$:

$$(a_1, \ldots, a_{k_i}) \in R_i \quad \text{iff} \quad (\varphi(a_1), \ldots, \varphi(a_{k_i})) \in S_i \qquad [5]$$

$\mathscr{A}$ and $\mathscr{B}$ are said to be 'homomorphic' if a homomorphism exists between A and B, If the homomorphism is a bijection, then it is an 'isomorphism.'

Isomorphic structures are, in a sense, identical, although their base sets A and B can be quite different, but each property of $\mathscr{A}$ expressible in terms of the relations R_i corresponds to a property of $\mathscr{B}$ expressible in terms of the relations S_j.

If the structures $\mathscr{A}$ and $\mathscr{B}$ are both ordered, i.e., $\mathscr{A} = (A, \precsim; R_i, i \in I)$ and $\mathscr{B} = (B, \precsim'; S_i, i \in I)$ where $\precsim$ and $\precsim$ are weak orders, then the homomorphism is sometimes called 'a monotonic' function. It satisfies

$$a_1 \leq a_2 \quad \text{iff} \quad \varphi(a_1) \precsim' \varphi(a_2)$$

If $\mathscr{A}$ is mapped homomorphically into a structure on the reals then the relation on $\mathbb{R}$ corresponding to $\precsim$ is usually, but not necessarily, the $\leq$ relation on $\mathbb{R}$. This situation is typical of representational measurement theory (*see* Measurement, Representational Theory of).

As an example, let $\mathbb{R}^+$ denote the positive reals and let $\mathscr{A} := (\mathbb{R}^+, \leq, \cdot)$ and $\mathscr{B} := (\mathbb{R}, \leq, +)$. Then $\varphi(x) := \log x$ is an isomorphism between these numerical structures.

As another example, let A be a set of players in a tournament and let $\precsim$ denote a ranking of these players with ties allowed. Here $\precsim$ is a weak order but in general it is not linear because of the possibility of ties. If $\mathscr{B} := (\mathbb{N}, \leq)$ with $\mathbb{N}$ the natural numbers, then the mapping φ which associates his or her place in the ranking with each player, is a homomorphism but not an isomorphism.

Homomorphisms can be concatenated provided the range of the first and the domain of the second coincide. More precisely, let $\mathscr{A} = (A, \precsim, R_i, i \in I)$, $\mathscr{B} = (B, \precsim, S_i, i \in I)$, and $\mathscr{C} = (C, \precsim, T, i \in I)$ be homomorphic structures with the homomorphisms

$$\varphi: A \to B \quad \text{and} \quad \psi: B \to C$$

where φ is surjective. Then $\mathscr{A}$ and $\mathscr{C}$ are homomorphic by the homomorphism $\xi := \psi \circ \varphi$. This fact is of particular importance when the structures are all identical; this case is considered in Section The Automorphism Group of an Ordered Relational Structure.

The Automorphism Group of an Ordered Relational Structure

An isomorphism which maps its domain structure onto itself is called an 'automorphism.' Let Aut $\mathscr{A}$ denote the set of automorphisms of a given structure $\mathscr{A}$. Clearly, Aut $\mathscr{A} \neq \varnothing$

because $\mathrm{id}_A \in \mathrm{Aut}\ \mathscr{A}$, i.e., the identity map is always an automorphism. If $\alpha, \beta \in \mathrm{Aut}\ \mathscr{A}$ then $\alpha \circ \beta \in \mathrm{Aut}\ \mathscr{A}$; furthermore, $\alpha^{-1} \in \mathrm{Aut}\ \mathscr{A}$. Thus $(\mathrm{Aut}\ \mathscr{A}, \circ)$ has the properties of a 'group,' i.e., a set with an operation on it which is associative, has an identity element (id_A in this case), and a right and left inverse (α^{-1}) Therefore $(\mathrm{Aut}\ \mathscr{A}, \circ)$ is called the 'automorphism group' of $\mathscr{A}$.

Modern measurement theory exploits the properties of the automorphism group very intensively. The main ideas on how this is done are now described.

The structure $\mathscr{A}$ is called 'homogeneous' if for each $a, b \in A$ there is an $\alpha \in \mathrm{Aut}\ \mathscr{A}$ such that $\alpha(a) = b$. The group and the structure are called 'n-homogeneous' if for any two n-tuples $a_1 \prec \ldots \prec a_n$ and $b_1 \prec \ldots \prec b_n$ there is at least one automorphism α such that $\alpha(a_i) = b_i$. Similarly, they are called 'n-unique' if for any two n-tuples $a_1 \prec \ldots \prec a_n$ and $b_1 \prec \ldots \prec b_n$ there is at most one automorphism α such that $\alpha(a_i) = b_i$. n-uniqueness can be reformulated as: if two automorphisms agree on n points then they are identical.

If M is the maximal homogeneity and N the minimal uniqueness of a structure, then the 'scale type' of $\mathscr{A}$ (or of Aut $\mathscr{A}$) is denoted by the pair (M, N). Clearly, one has $M \leq N$. $N = \infty$ means that there is no minimal degree of uniqueness. A structure with $N < \infty$ is called 'finitely unique.'

One of the most important results of measurement theory in the 1980s is the following theorem developed by Narens (1981) and Alper (1985, 1987).

Theorem 1 (Alper/Narens Theorem)
Let $A = \mathbb{R}$ *with* $\mathscr{A}$ *homogeneous and finitely unique. Then it is of scale type* (1, 1), (1, 2) or (2, 2). Type (1, 1) is a ratio scale and type (2, 2) an interval scale (see Section Examples of Ordered Relational Structures of Measurement, Representational Theory of).

The importance of this theorem for measurement theory is discussed in the articles on measurement theory (*see* Measurement, Representational Theory of). Suck (2000) proved a partial generalization for ordered structures with an arbitrary base set. Essentially, his result shows that for scale type (N, N), in many, though not all cases, the Alper/Narens Theorem remains true if the base set A of the structure is different from $\mathbb{R}$.

Order Topology

If one wants to exploit the power of the continuity concept for the investigation of ordered relational structures, then one must construct a 'topology' on A which is compatible with the order relation and, if possible, with the other relations as well.

A topology of A is a collection $\mathscr{T}$ of subsets of A, called the 'open sets,' such that the following three conditions are satisfied:

(T1) $\emptyset \in \mathscr{T}$ and $A \in \mathscr{T}$.

(T2) If $\mathscr{S} \subseteq \mathscr{T}$ then $\bigcup_{T \in \mathscr{S}} T \in \mathscr{T}$.

(T3) if $\mathscr{S}$ is a finite subset of $\mathscr{T}$ then also $\bigcap_{T \in \mathscr{S}} T \in \mathscr{T}$

The structure $(A, \mathscr{T})$ is a 'topological space.' For a development of the theory of topological space see Kelley (1955) or Dugundji (1966). The most important topological space is constructed on $\mathbb{R}$ by defining as open all subsets of $\mathbb{R}$ which are arbitrary unions of open intervals. This construction can be carried out in any ordered structure and is called the 'order topology' (see below). Thus, any $\mathscr{A}$ of the kind considered in this article can be regarded as a topological space endowed with the order topology.

In topological spaces the well-known concepts of convergence, limits, and continuity can be defined, and in this way, far reaching generalizations of familiar theorems of analysis are available in the theory of ordered relational structures.

We give the topological definition of 'continuity.' Let $(A, \mathscr{T}_A)$ and $(B, \mathscr{T}_B)$ be topological spaces. A function $f: A \to B$ is 'continuous' if for all $U \in \mathscr{T}_B$ the preimage under f, i.e., the set $f^{-1}(U) := \{a \in A; f(a) \in U\}$ is in $\mathscr{T}_A$.

Next, we are going to define the 'order topology' of an ordered structure $\mathscr{A}$. We assume that A does not contain a maximal or a minimal element. We define: for all $a, b \in A$

$$(a, b) := \{x \in A; a \prec x \prec b\}$$

$$[a, b] := \{x \in A; a \precsim x \precsim b\}$$

$$(0, a) := \{x \in A; x \prec a\}$$

$$(a, \infty) := \{x \in A; a \prec x\}$$

and call these sets intervals (with respect to $\precsim$). Note that the symbols 0, ∞ do not denote elements of A.

The intervals $[a, b)$, $(a, b]$, $(0, a]$, and $[a, \infty)$ are defined analogously. (a, b), $(0, a)$, and (a, ∞) are referred to as 'open intervals.' The open intervals are used as a 'basis' for the order topology denoted by $\mathscr{T}_{\precsim}$, i.e., $\mathscr{T}_{\precsim}$ is the collection of those subsets of A which can be generated by union from an arbitrary set of open intervals.

The construction of the order topology for an ordered relational structure is useful when the other relations of $\mathscr{A}$ are in some sense compatible with $\mathscr{T}_{\precsim}$; e.g., when there is an operation among the R_i then it should be continuous.

If $\precsim$ is a linear order, $\mathscr{T}_{\precsim}$ is easily seen to separate points, i.e., for all distinct $a, b \in A$ there are open and disjoint sets U, V such that $a \in U$ and $b \in V$. In particular, consider $a \prec b$ then, if $z \in (a, b)$ exists, $(0, z)$ and (z, ∞) are such sets; if $(a, b) = \emptyset$, then $(0, b) \cap (a, \infty) = \emptyset$ and $a \in (0, b)$ and $b \in (a, \infty)$. Technically, such a space is called a 'Hausdorff space.'

A bijective and continuous map $f: A \to B$ between topological spaces $(A, \mathscr{T}_A)$ and $(B, \mathscr{T}_B)$ is a *homeomorphism* if its inverse is also continuous. Topology is mainly concerned with properties of spaces which are shared by all spaces that are homeomorphic to a given one. These are called 'invariants' of the space.

Specializing this concept on order topologies, we observe: Isomorphic linear orderings are homeomorphic with respect to the order topologies and an isomorphism is a homeomorphism. Formulating this result as a theorem one gets:

Theorem 2
Let $(A, \precsim_{\mathscr{A}})$ *and* $(B, \precsim_{\mathscr{B}})$ *be two linear orderings and* $f: A \to B$ *strictly monotonic and surjective. Then* f *is*

a homeomorphism with respect to the order topologies induced by $\precsim_{\mathscr{A}}$ *on A and* $\precsim_{\mathscr{B}}$ *on B.*

It follows from Theorem 2 that automorphisms of a structure $\mathscr{A} = (A, \leq, R_i, i \in I)$ are homeomorphisms of $(A, \mathscr{T}_{\precsim})$ onto itself.

Summarizing, we note that the order topology carries a lot of information about an ordered relational structure. Despite this fact, it has not been used very much in measurement theory until very recently. Wakker (1988) pointed out that in many cases the algebraic conditions used by Krantz et al. (1971) and others are more general than topological ones. As long as the use of topological concepts is restricted to the order topology no extra conditions need be imposed. In some modern investigations the order topology could be put to use as a fruitful tool. For instance, even the topological properties of the automorphism group can play an important role (Suck, 1998, 2000).

Finally, it should be mentioned that the power of topological methods shows up in infinite structures (although the definitions are not restricted to this case). Some approaches to measurement try to avoid such structures, especially the continuum. As an example, we refer to Sommer and Suppes (1997).

Completion of Structures

The article on partial orders introduces the 'McNeille completion' of a partial order (*see* Partial Orders). This construction is also useful for ordered structures in the sense of the present article. The property of existence of infimum and supremum is equivalent to the existence of a cut element for each 'Dedekind cut.' It is called 'Dedekind completeness' (cf Narens, 1985: p. 16).

If $\mathscr{A}$ is an ordered relational structure then the McNeille completion of $(A, \precsim)$ is 'Dedekind complete.' However, a major problem arises if one wants to extend the other relations of $\mathscr{A}$, i.e., the R_i for $i \in I$, to the complete superset of A. There may exist no extension at all, or too many – more than one is already too many; Narens (1985) and Cohen (1988) investigated this problem for so-called positive concatenation structures. The results are discussed in Luce et al. (1990) in Chap. 19.4.

In the context of the order topology Dedekind completeness is equivalent to 'connectedness' in the topological sense, i.e., there are no two disjoint open sets U, V such that $A = U \cup V$. Ovchinnikov (1996) proved the surprising result that a homogeneous structure $(A, \precsim)$ with a linear order $\precsim$ has either a connected order topology or each of its maximal connected subsets consist of one element only. This result has far reaching consequences for ordered relational structures and their automorphism groups. It is at the heart of Suck's (2000) generalization of the Alper/Narens result. Thus, if a completion is feasible then many properties of the structure follow from this theory.

Abstract

The geography of organization denotes the interdisciplinary study of the spatial aspects of organizations and processes of organizing. Geography as well as organization and management studies are the major fields to contribute to this area. Three major strands of research can be distinguished. One focuses on 'organizations in space' and how organizational action transforms space and vice versa. The second one looks inside organizations and is interested in how space shapes organizational life. The third one moves away from the organization as an entity but rather centers on how processes of organizing create emergent sociomaterial orders.

The geography of organization refers to the interdisciplinary study of the spatial aspects of organizations and processes of organizing. It analyzes how space and organization interact and shape each other. 'Organization' in the singular is the term that encompasses both 'organizations' – associations of human and nonhuman elements that are meant to work toward specific goals – as well as 'organizing' – the practices of establishing these associations. The term 'institution,' by contrast, which can sometimes be found in the geographical literature as a synonym for organization, is reserved for the dominant understanding in political science that sees institutions as the formal and informal rules that structure social and political behavior.

The intersection of space and organizations has grown in importance due to the proliferation of organizations worldwide and their rising significance in all aspects of contemporary societies. At the same time, processes of globalization and attendant time-space compression have also altered the role of space for organizational activities. Rather than a discernible field *sui generis*, the geography of organization is more a shared interest in some common themes. Major contributions to studying the geography of organization have originated from human geography as well as from organization and management studies. Both fields have experienced a surging interest in space and organization, respectively, in the 2000s (in organization and management studies, for example, Clegg and Kornberger, 2006; Dale and Burrell, 2008; Hernes, 2004; in geography Müller, 2012; Philo and Parr, 2000).

For a long time, the implicit division of labor between geography on the one hand and organization and management studies on the other was such that geography focused on 'organizations in space,' treating the organization as a black box, whereas organization and management studies were interested in 'space in organizations,' however, often ignoring what was going on outside the organization. Organization and management scholars studied the role of space for activities in organizations, whereas geographers tended to be interested in the external implications of the activities of organizations for space. This division has become blurred with the embrace of poststructuralist approaches that are concerned with organizing in a broader sense than with organizations as discernible units. This article brings together the literature from the two fields, charting the major lines of flight and exploring commonalities and differences. In so doing, it also seeks to tap the potential for closer dialog for two literatures that have hitherto often followed rather separate trajectories.

Theoretical Perspectives

Three major different social theoretical perspectives have characterized work on the geography of organizations: positivism, critical realism, and poststructuralism. **Table 1** provides a schematic overview for a rough first orientation, although it should be acknowledged that the boundaries often blur.

Table 1 Major theoretical perspectives on the geography of organization

	Positivism	*Critical realism*	*Poststructuralism*
Approaches	Spatial science Functionalism Rational choice	Institutionalism Structuration Critical theory	Discourse theory Practice theory Actor-network theory Embodiment
Organization	Discrete, bounded entity	Embedded entity	Temporarily fixed, constructed entity
Ambition	Mapping the organization	Contextualizing the organization	Deconstructing organization
Key question	What are the spatial patterns of organizational relationships?	How is the organization related to its socioeconomic context?	How is organization as a precarious order maintained and subverted across space?
Methods	Descriptive and inferential statistics GIS Survey research	Structured and open interviews Participant observation Descriptive statistics	Participant observation Open interviews Text analysis Visual analysis

Adapted from Del Casino Jr., V., Grimes, A.J., Hanna, S.P., Jones III, J.P., 2000. Methodological frameworks for the geography of organizations. Geoforum 31, 523–538.

The positivist understanding sees organizations as bounded, discrete units with a fixed membership and a defined set of rules. Going back to Weber (1922), it stresses the organization as an ordered and stable entity with predictable routines and rules. It is most interested in the spatial patterns of organizational relationships, either in the organization itself or with its environment, and is associated with approaches such as spatial science and rational choice. This perspective can be descriptive, mapping spatial patterns, but it can also be explanatory, trying to predict spatial patterns through organizational variables or vice versa. While dominant until the 1970s, not least fueled by the quantitative revolution of the 1960s, the positivist perspective has lost ground since then with turns toward social and critical theory in both geography and organization and management studies.

The critical realist perspective dissolves the assumption of the boundedness of organizations in favor of viewing them as linked up with wider social, economic, and political structures. The actions of organizations thus cannot be studied without taking into account the relations with their surrounding. This understanding owes much to Granovetter's (1985) notion of embeddedness, but also to Giddens' (1984) structuration theory that privileges neither structural nor agential explanations of organizational action. Veering away from the quantitative description and explanation of spatial patterns, the critical realist perspective increasingly employs qualitative methods such as semistructured interviews in addition to quantitative methods. It has been particularly useful for conceptualizing the relationship between the organization as an actor and space as the variable context in which it is embedded and enjoys particular popularity in economic geography.

The poststructuralist understanding moves from a focus on 'the organization' as entity to 'organization' as a temporarily fixed but in general ephemeral effect of the process of organizing. It is thus more interested in the becoming than in the being of organization and in the processes that bring about organization in the first place. It was Weick (1979) who pioneered this shift in attention in the studies of organization with his focus on the 'enactment' of organization. This perspective sees organization as unbounded in time and space: it is an emergent phenomenon, multiple, and amorphous. Deconstructing how this precarious order is temporarily stabilized or subverted is the central ambition of such a poststructuralist perspective that draws on a range of thinkers from Foucault to Deleuze, Latour, and Lefebvre. It has been the driving force behind the spatial turn in organization and management studies since the 2000s and has also enjoyed increasing popularity in geography with the reception of more-than-representational forms of theorizing and the concomitant focus on embodiment. However, it also encompasses variants of discourse analysis that concentrate on the meaning-making in and of organizations and thus on the semiotic side of social life.

Types of Organizations

The types of organizations that are studied in the geography of organization vary greatly. Organization and management studies as well as economic geography are most interested in firms as pivotal actors in the modern economy. In organization and management studies, this empirical focus is related to the common affiliation of the field with business schools. Transnational Corporations (TNCs) have enjoyed particular attention in economic geography, because their far-flung, intricate global networks make them ideal cases to study the geography of organization. However, empirical interest has branched out in recent years to other organizations that partake in economic activity, such as trade unions, not-for-profit organizations or public administration, and service organizations.

Political geography devotes more attention to organizations involved in politics, whether that is institutionalized big P Politics or the small p politics of social agonism and contestation. While the state and its multiple organizational manifestations have been at the center of interest for a long time (see State, Geography of), other organizations such as international and transnational organizations, NGOs, grassroots movements, schools, or the church have broadened the array of actors that are studied. In social and cultural as well as in urban geography, the range of organizations encompasses the various aspects of public administration and service as well as social movements, neighborhood and community organizations, and NGOs. Here, some organizations also figure under the moniker of 'institutions,' in particular hospitals, asylums, schools, and so on.

Organizations in Space

Research on organizations in space asks how organizational action is mediated through and across space as well as how it transforms space and vice versa. This research area has attracted increasing attention not least due to the growing need of organizational processes to be coordinated across space in the wake of globalization, but also because of the major influence organizations have on spatial patterns of the economy. It is no surprise then that the role of organizations in space is a key ingredient in many geographical theories, in particular in economic geography. Storper's (1997) 'holy trinity' of technologies, organizations, and territories equates organizations with firms and production systems. He follows Coase in seeing the major rationale of organizations in reducing transaction costs. The main goal of organizations then is to internalize and coordinate action in the economy. To this end, organizations establish a system of rules to adhere to, thus creating conventions and relations over and above mere traded transactions. Bathelt and Glückler (2003), too, have organizations as one of their four ions of a relational economic geography, alongside interaction, innovation, and evolution. For them, organizations exist to coordinate economic inputs across an increasingly differentiated spatial division of economic activity in the world, while at the same time being embedded in local social, cultural, and institutional structures. It is this tension between the recursive relationship of organization and space that characterizes work on organizations in space.

Organizations Forming Space

One strand of research seeks to explain spatial patterns, whether economic, social, or political, through the study of

organizations and organizational structures. Organizations here figure as an alternative *explanans* to complement those of individual choice and capitalist market forces. Among others, scholars have discussed the influence of government organizations on such things as the patterns of agricultural activity, migration, political boundaries, natural resource exploitation, or industrial location (e.g., Flowerdew, 1982; Scott, 1998). A groundbreaking study of the way that organizations impact on geography is Selznick's (1949) *TVA and the Grass Roots*. It is an in-depth analysis of the organizational rationalities of the Tennessee Valley Authority (TVA), a government agency that was set up in 1933 to facilitate resource development and regional planning in that area and today is the largest regional planning association in the United States. Selznick considers how the TVA coopted local residents and organizations into its land use policy, which were to fundamentally transform the spatial pattern of the Tennessee Valley with the construction of multiple dams and navigation channels and the introduction of new agricultural and forest policies.

In economic geography, the geography of enterprises, or corporate geography, sought to relate the spatial patterns of economic activity to decision making in organizations. Corporate strategies, such as cost leadership or differentiation, or vertical and horizontal integration versus disintegration have an effect on the location and clustering of production activities and thus on regional economies. The large corporation with a centralized, hierarchical structure became the archetypal organization to be studied under this rubric. Yet, corporate geography came under fire for lacking proper theoretical foundation, having no additional explanatory power over the forces of market capitalism, and being too preoccupied with the single large corporation (Walker, 1989). As a response, scholarship moved to embrace the concept of the network, which recognized the increasing differentiation of organizational forms and the fraying boundaries of organizations (Dicken and Thrift, 1992). Enjoying considerable prominence in economic geography, a set of approaches has sought to conceptualize the spatially dispersed nature of the production of commodities and services in the global economy. Global production networks and global value chains seek to capture the flows that bind headquarters and subsidiaries or customers and suppliers together for the sourcing and distribution of products (Henderson et al., 2002). Yet again, however, the prominent concept of the lead firm, which coordinates and controls operations across several countries, focuses on one large corporation that has the power to manipulate global space.

Space forming Organizations

The relation between *explanans* and *explanandum* is inverted in the second strand of research which considers not the effects of organizations on space but that of space on organizations. It acknowledges that organizations do not exist as quasi-independent entities that are isolated from the space surrounding them (Dicken and Thrift, 1992). The central idea is that of the embeddedness of organizations, i.e., the influence of institutions outside the organization on organizational action (Hess, 2004). Here, the term institutional thickness has been used to describe an integrated web of institutions such as enterprise support systems, political institutions, and social citizenship that create a shared sense of purpose and synergies of interaction between organizations.

In what has become known as the 'new regionalism' the institutional thickness of regions as well as the close proximity of organizations to each other is thought to grant a competitive edge to firms located there. This assumption is captured in a range of concepts such as the cluster, learning region, creative milieu, or industrial district, which are assumed to enhance interorganizational trust and boost learning and innovation in organizations located there. This spatial proximity between organizations is considered of particular importance for the exchange of tacit knowledge, which is at the heart of many innovation processes. Saxenian's (1996) comparison of the Silicon Valley with the Boston Route 128 cluster, for example, attributes the comparative success of Silicon Valley precisely to the presence of advantageous regional effects on organizational action. Geographers have celebrated this new regionalism as signifying the continued importance of space for organizational success, despite predictions of the death of distance in the age of globalization.

Producing Spatial Representations

A third sense in which organizations are involved in space relates to the production of representations of space. This strand of research starts from the assumption that organizations created shared symbolic meanings of spaces. Studies in this vein tend to operate with the concept of discourse or other semiotic approaches and are concerned with how language attaches differential meaning to space, which, in turn, might influence social action. Some pinpoint single organizations, such as government agencies, the EU, or the media, while others examine the representations produced by a multitude of different organizations but with respect to the same spatial category, such as 'Eastern Europe' or 'Africa.' An illustrative example of this category is the analysis of organizational discourses in the wake of 9/11 (Dahlman and Brunn, 2003). The study makes the case for recognizing NGOs as "important agents in the production of ideational content and the circulation of contemporary global visions and political (re)orderings" (p. 256). On the basis of press releases and public statements immediately after 9/11 from a broad variety of 23 organizations, ranging from the WWF to the World Bank, the IOC, and the World Council of Churches, the authors perform a discourse analysis of the spatial framing of the terrorist events.

Space in Organizations

For a long time, geography has been interested in the effects and rules that organizations produce, which is reflected through the frequent use of the term 'institution.' The mechanisms and processes of rule production within organizations, however, have tended to escape scrutiny. This predicament of treating the organization as a black box has drawn increasing critique in different geographical subdisciplines, provoking calls to examine and theorize what is going on inside organizations (Müller, 2012; Taylor and Asheim, 2001). This kind of

research has been the staple of organization and management studies. Space, however, did not explicitly appear on its agenda until the 2000s. When it made its entry, it happened with a flourish, prompting talk about a 'spatial turn' in the discipline and even attempts at rethinking organization through space, since "any act of organizing is about creating a space for human action and interaction" (Hernes, 2004: 11).

Ordering Space

Much of the concern with space in organizations has revolved around how the ordering of space can become a source of power. Work in this tradition often connects to critical management studies in highlighting how management can produce unequal and exploitative relations. Foucault and Lefebvre act as the major sources of theoretical inspiration. For Foucault, "discipline proceeds from the distribution of individuals in space … [it] organizes an analytical space" (Foucault, 1979[1975]: 141, 145), a dictum that he exemplified in his work on the prison as a panopticon and on schools as forming docile bodies. What has attracted most attention in Lefebvre's work is the dialectic of the spatial triad of conceived space (*le conçu*), perceived space (*le perçu*), and lived space (*le vécu*) (Lefebvre, 1991[1974]). Conceived space corresponds more or less to Foucault's idea of space: the spatial order that relations of production impose, expressed in plans, calculations, and models. Perceived space refers to spatial practices and the everyday appropriation of space through routines and rituals that reproduce space. Lived space, finally, represents the dynamic element, in which opportunities for difference and subversion arise that overflow the rigid spatial models of conceived space.

At the center of attention is the question of how space shapes organizational life and vice versa. The stress falls on the material aspects of space, or physical space, as it manifests itself in office layouts or the architecture of buildings (Dale and Burrell, 2008; van Marrewijk and Yanow, 2010). This (re-) discovery of material space in organization and management studies is often phrased as engaging in a dialog with the discipline of architecture rather than that of geography (Clegg and Kornberger, 2006; Kornberger and Clegg, 2004). This might be because geography, until recently, has rather sought to overcome the notion of physical space, emphasizing the constructedness and malleability of space. Claims about how space shapes organizational functions stir unpleasant memories of geographical determinism with geographers.

This strand of research examines how the material spaces in an organization are often enlisted to increase control over staff, enhance productivity, or save costs under the disguise of a rhetoric of making office space more livable and worker-friendly. An example is the enchantment of modern management with open plan offices, which have done away with walls in office buildings. The intention of open plan offices is to buttress information exchange and communication and increase the identification with the organization. At the same time, it also facilitates surveillance of staff through placing people and screens in plain view of the panoptic gaze. The original intentions of this conceived space – to follow Lefebvre's terminology – are often subverted, however, in the everyday practices of the social appropriation of it. Workers sometimes improvise makeshift partitions between workplaces with files and books or use earplugs to escape the constant background noise of the office. The continuous circulation of people, fueled through policies of hot-desking, often contributes to social withdrawal rather than to the desired social integration and exchange. In this sense, conceived space does not determine organizational life, but there is a recursive relationship in which its social appropriation leads to initially unintended effects.

Folding Space

While the research on ordering space makes much of distances and spatial partitioning, research on folding space takes the opposite tack: it is interested in how large physical distances are reduced to become small. Such an approach owes much to actor-network theory (ANT) and Serres and Latour's (1995) notion of topological space, where distance is a function of the length of a relation between two elements and as such not pre-given. Latour and Serres use this metaphor of 'folding space' to liken space to a handkerchief which can be folded and crumpled so that two points that were distant in the beginning end up close together. For example, I can be further away from the colleague who sits in the next cubicle but works for a different department than from a collaborator who works thousands of kilometers away but who is on my Skype list. The possibilities of folding space in organizations have increased with new channels of communication such as e-mail and social media, which allow people to feel connected and develop a form of sociality across vast physical distances, as well as with cheaper long-distance travel (see Globalization, Geographical Aspects). We thus increasingly find teams that are not co-located but rather work on the same project from different locations across the world.

The notion of folding space is of particular relevance for organizational arrangements where elements from different locations need to come together to produce organizational action. This empirical phenomenon has been captured in concepts such as that of the 'community of practice' and others that revolve around a distanciated sociology of learning (Amin and Cohendet, 2004: Chapter 5). In communities of practice, knowledge is created and passed on in relationships between people, and learning occurs through repeated interaction. "What allows members [of communities of practice] to share knowledge is not the choice of a specific form of communication … but the existence of a shared practice – a common set of situations, problems and perspectives" (Wenger et al., 2002: 25). Communities of practice therefore do not have to consist of localized individuals, but can be made up of a network of individuals dispersed around the globe that are nevertheless tied together through common relations. This assumption of knowledge relations stretched over long distances complements but does not supplant that of the territorial embeddedness of learning and innovation, which stresses the importance of spatial proximity.

Organizations have an active part to play in this folding of space, for the stretching and maintenance of relations over long distances requires much effort. Organizations provide the informational infrastructure, be it e-mail, wikis, intranets, project management software, or video conferencing

equipment, but also facilitate the moving of human bodies between places through business travel. Forms and documents of all manners act as intermediaries between different locations, since they can be moved easily, and help align organizational action. But organizations also create a shared practice through orienting staff toward a common goal, establishing formal and informal codes of conduct and social practices – often referred to as organizational culture. Examining how those relations across distance are established and maintained, what kind of organizational action they result in, and where they break down is the key interest of research in this mold. For that purpose, researchers often adopt a research strategy of 'following the thing,' reconstructing the networks people and things weave as they move from place to place and enroll new elements for organizational action.

Organizing Space

Emerging with a turn toward poststructuralist theorizing, the *process* of organizing has attracted increasing attention. This has implied a move away from the organization as a self-enclosed entity and distinctive focus of research, broadening the empirical scope of interest and also the possibilities for convergence between geography and organization and management studies. The central question here is how organization as a precarious order is maintained and subverted across space. 'Organizing' thus is often used as a synonym for 'ordering,' i.e., arranging things and people for a certain amount of time. This shift foregrounds the spontaneous, ad hoc character of organization and how it is actualized in social practices. For Thrift and Olds (1996: 319–320), four implications result from this shift. First, organization is improvised and tentative and not as goal-oriented and purposive as much of the literature has tended to assume. Organizational action has a haphazard character and affords a rather partial view of the world. Second, organization is constituted in action and talked into being and thus needs continued maintenance, rather than existing as an unproblematic a priori. Third, organization is always open and has fuzzy boundaries, bringing in new elements, while discarding others at the same time. Fourth, certain interactional structures are linked to organizational forms that cannot be adequately described with the existing notion of the organization. This applies, for example, to the precarious and dispersed nature of projects and social movements.

For the theoretical underpinning of this understanding of organizing, research has turned to inspiration from a heterogeneous range of authors such as Derrida, Deleuze, and Guattari, actor-network theorists such as Latour, and phenomenologists such as Spinoza. Three ideas can be highlighted as central. One is that of the *performativity* of organizing, whereby organization is enacted through repetitive practice. This calls for a shift of attention to the mundane practices through which organization is brought into being at the level of the individual, which is in tune with the budding interest in theories of practice. It reverses the idea that organizations give rise to certain actions, claiming that instead actions constitute organization. This assumption is encapsulated in Kafka's often-cited fragmentary novel *Der Prozeß*, where the very actions of the protagonist K. give birth to the trial and the court at which it is pursued in the first place.

The second idea is that of taking *materiality* seriously, both in the sense of giving more weight to things and to the corporeality of the human body and its senses. The claim that 'things matter' recognizes that organization is a sociomaterial accomplishment, in which things – whether mundane such as partition walls or complex such as software – often provide the cohesive glue to make organizational arrangements durable at least for some time. For Latour, for example, technology is society made durable and in his concept of agencements (assemblages) Deleuze equally insists that the combination of social *and* material elements creates action. This insight breaks with the tradition of seeing organizations as associations of individuals and skirting over the role of the material world, which often served as a mere backdrop. Grappling with the specific materiality of the human body involves treating it as a living organism with all the senses and forces that work through it. Giving due attention to affects such as fear or desire calls the concept of the rational, calculating individual into question, but at the same time opens up new perspectives on what makes organization durable across space or fall apart. However, it also throws up challenges about the research methods with which to approach such phenomena as affect, which often seem to be too elusive to be captured in interviews, for example.

Multiplicity, a notion at the heart of Deleuze's thought, is the third central idea of research on the processes of organizing space and refers to the precarious, contingent nature of organization, in which arrangements could always be otherwise. It thus has an avowedly political component in that it affirms the openness of the current state of affairs to political contestation, since there is no natural, generative order of things. A concern with organizing thus goes lockstep with an interest in how orders are always temporary and subverted, how power is necessarily limited and much escapes its structuring effect and how creativity is at work in unexpected places. But it also implicates an ethical call for the researcher to abandon a position of purportedly detached observation to engage in what has been called ontological politics, i.e., to think about the worlds we want to help make through our research.

Such efforts to push the boundaries of research on the geography of organization have gelled into studies that sweep across a broad range of empirical territory. They have encompassed a reliving of the riveting experience of slow-motion video as a corporeal sensitization for the minutiae of affect in everyday life (Beyes and Steyaert, 2012) or the development of new sensitivities for the experiential spaces of a voluntary welfare agency, with their fleeting and affective encounters (Conradson, 2003). The established boundaries between geographers and scholars of organization and management studies have increasingly become erased and transgressed in the course of this and there is increasing recognition of each other's work. Yet much remains to be done in the years to come to bring the conceptual promises and ambitions of this research direction to full empirical fruition.

Abstract

Organizations have been studied from many disciplinary perspectives and at many levels of analysis. This article focuses on organizations as distinct units, covering the twentieth-century evolution of the study of organizations and briefly summarizing the major theoretical approaches. We emphasize the shift from a focus on organizations as bounded units to organizing as a process and conclude with contemporary challenges for organization theory.

Organizations

Organizations are a defining feature of modern societies. Modern societies are distinguished from traditional ones in part by the numbers and variety of organizations in existence, and their utilization to support collective action in every sector. Organizations are both contexts for the actions of individuals and groups, and collective actors in their own right. Some, such as corporations, are given legal recognition and constituted so as to own and dispose off the property, enter into binding contracts, and mobilize effort in the pursuit of specified goals. Organizations can be formatted to increase the reliability of behavior, but in doing so, they often become rigid and constraining. They also are able to provide greater accountability, maintaining records of how things are done and by whom, but in doing so, may become overly procedural and legalistic. Today's organizations, operating in a highly rationalized and dynamic environment, face different challenges than early organizations confronting a more traditional and stable context. Conceptions of organizations, theoretical perspectives, and favored levels of analysis undergo change, in part because organizations and organizing processes themselves have changed.

Organizations have been studied from many disciplinary perspectives and at many levels of analysis. Psychologists, sociologists, political scientists, and economists have all made central contributions to the understanding of organizations. Psychologists typically study individuals, dyads, and groups within an organizational context to uncover distinctive features of organizational behavior, such as how the design of jobs or pay systems influences individual motivation, or how groups of managers make decisions. Political scientists have extended the study of decision making to the design of organizations and the pathologies of bureaucracy. Sociologists examine both the structures of individual organizations, their relations with other organizations, and aggregate features of organizational populations and fields. Economists study how markets influence the shape of organizations – where they place their boundaries, how they are owned and governed – and how firms interact in industries. Thus, organizational scholars span a range of units of analysis, from individuals and groups, to departments and divisions, to organizations and industries, to networks and fields, and even to the level of the nation-state and the global system itself. In each case, the vocabulary and theoretical toolkit varies according to the level, as do the questions considered 'interesting.'

This article focuses on organizations as distinct units (i.e., on 'organization theory') but it also acknowledges that there are alternative perspectives and trade-offs involved in choosing one focus rather than another. It first describes how dominant theoretical views of organizations evolved over the twentieth century. It then analyzes the distinguishing features of organization from a substantivist and a relational perspective. Next it discusses different views on the origins of organizations and how different levels of analysis channel different approaches to their object of study. Finally, it concludes with a discussion of new directions in the study of organizations.

Evolving Perspectives on Organizations

Three definitional perspectives on organizations, each embracing a number of schools, have been pervasive during the twentieth century in organizational studies, and each has been animated by its own dominant metaphor for organizations (Scott and Davis, 2007). The 'rational system' model of organizations was the dominant perspective from early in this century to the 1930s. Organizations are viewed as rationally designed instruments for the attainment of specific goals. A mechanical model provides the guiding image and emphasis is placed on those features that differentiate organizations from other social groups, such as communities or families. Exemplars include the 'scientific management' approach of F.W. Taylor, Weber's theory of bureaucracy (1968), and Simon's model of (boundedly) rational decision-making hierarchies (March and Simon, 1958). The twin attributes of goal specificity and formalization – the deliberate design of roles and social structures – are privileged.

The 'natural system' model of organizations emerged during the 1930s and became dominant in the scholarly community in the 1940s and 1950s. Organizations were viewed as social groups whose participants are joined by common purpose and informal ties, but whose primary goal is the survival of the system. Rational, formal attributes were de-emphasized as attention was focused on interpersonal ties and leadership. An

organic image supplanted that of the well-oiled machine; not distinguishing elements, but rather those common to all social groups were emphasized.

During the 1960s, general systems theory swept over the field of organization studies giving rise to the 'open system' model of organization. This model emphasized the extent to which organizations were dependent on and penetrated by facets and forces in the wider environment. By contrast, previous models were exposed as giving insufficient attention to actors and forces external to system boundaries. But as open system models surged into the arena, they quickly were coupled with, first, rational, and then natural system concerns (Scott and Davis, 2007). Thus, rational-open theorists like Thompson (1967) and Lawrence and Lorsch (1967) sought to explain how organizations could attempt to behave rationally while also open to their environments; March and Simon (1958) considered how decision rules can be adjusted to accommodate greater amounts of uncertainty; and Williamson (1975) theorized that organizations arise and develop more complex governance systems to deal with increasing amounts of uncertainly and complexity. Contingency theory, decision-making theory, and transaction cost theory represent attempts to combine rational and open systems conceptions.

These developments dominated well into the 1970s, but they then were joined by a resurgence of natural system theorists attempting to incorporate and take into account open system insights. Principal approaches included *socio-technical systems* theory, emphasizing the need to design technologies to take into account human and social factors, and *resource-dependence* theory, as developed by Pfeffer and Salancik (1978), which stressed the ways in which economic (resource-based) dependencies generated power problems that, in turn, were addressed by political solutions. In general, organizations confronted by increasing levels of interdependence respond by creating more encompassing coordinative and governance systems. *Population ecology* models (Hannan and Freeman, 1989) examine the ways in which similar types of organizations compete for scarce resources within the same environmental niche. And *institutional theorists* (Meyer and Rowan, 1977; DiMaggio and Powell, 1983) consider the effects of wider cultural rules and normative structures on the emergence and *legitimation* of organizations.

Thus, conceptions of organizations have been influenced by the theoretical stance of scholars, as debates revolved around two axes: (1) the extent to which organizations are means – disposable, deliberately designed instruments for goal attainment – or value-impregnated, ends in themselves and (2) whether organizations are self-sufficient, relatively insulated forms or substantially constituted, influenced, and penetrated by the wider environment.

Why Do Organizations Exist, and What Distinguishes Them?

Max Weber, who provided a theoretical foundation for much subsequent work, was among the first social theorists to recognize and attempt to characterize the features that distinguished organizations from other social groupings. First, a 'legitimate order' is a social relation oriented to a normative framework or set of maxims viewed as obligatory (Weber, 1922/1968: pp. 26–53). Social relations vary in the extent to which they are open or closed, that is, limiting access to outsiders. 'Organizations' (Verband) are social relationships that are closed, with enforced boundaries between the inside and outside. 'Enterprises' (Betreib) are organizations that have developed a system of continuous purposive activity directed to specified goals; and a 'formal organization' (Betriebsverband) is an enterprise based on associative relations resting on rationally motivated adjustments of interests rather than on communal ties, which are based on kinship or the subjective feelings of the parties. The two latter definitions have been employed widely by subsequent scholars.

Chester Barnard, perhaps the most influential early American organizational theorist, was a telephone executive who drew on his own practical managerial experiences to develop his conception of the distinctive properties of organizations. Barnard (1938) emphasized the physical, biological, and psychological limitations of individual actors, limitations that greatly constrain their ability to make intelligent choices. Cooperative systems arise to enable individuals to collectively pursue a given purpose, the purpose acting to both support and constrain individual choice and decision making. Such systems are 'effective' to the extent that they achieve their purpose; they are 'efficient' if they satisfy the motives of individual participants. To be viable, systems must induce participants to make contributions; thus, only efficient systems can survive. Organizations represent a distinctive type of cooperative system: a 'formal organization' is 'that kind of cooperation among men that is conscious, deliberate, purposeful' (p. 4), although all organizations incorporate both formal and informal systems.

Weber's intellectual descendants include a host of sociological scholars, from Parsons to Etzioni, Blau, and Albrow. All of these theorists follow Weber in emphasizing goal specificity and formalization as distinguishing features of organizations and in recognizing the importance of power and hierarchy both in defining goals and controlling access and specifying the terms of participation. Barnard's followers encompass a diverse collection of researchers, including political scientists Simon and March, economists Arrow and Williamson, and sociologists Selznick and Perrow. Devotees from political science and economics embrace Barnard's view of organizations as arising from the limitations of individuals – physical, but more important, cognitive constraints – organizational structures and processes acting to both inform and channel their decision making. These same theorists also stress the rationality of individuals, insisting that their participation and willingness to make contributions is contingent on the continuing receipt of appropriate inducements. A modified version of Barnard's approach, developed by Cyert and March (1963), views organizations as coalitions of interests, with diverse parties vying for dominance. Sociologists, by contrast, focus on Barnard's recognition of the motivating power of purpose and the ways in which organizational structures and procedures themselves become infused with value, so that, as both instruments and ends in themselves, survival of the organization becomes an overriding goal for participants (Selznick, 1949). Organizations are observed to dispense with

specific objectives when their pursuit undermines organizational viability.

Relational Views of Organizations

Although Weber and his followers have viewed organizations as substantive entities, emphasizing boundaries and goals, other theorists have taken a more relational perspective focused on 'organizing' rather than 'organization.' Karl Weick was a major early proponent of a more relational conception of organizations:

> We observe either an ongoing process that appears "frozen" and steady because it is glimpsed only briefly, or we observe that the process is continuously changing if we watch for a longer span of time. The point is that the crucial events to be explained are processes, their structuring, modification, and dissolving. (Weick, 1969: p. 16)

This stance has been embraced and elaborated by theorists such as Giddens (1984), who proposed that 'structure' be reconceptualized as 'structuration' – the continual production and reproduction of resources and rules or schemas – as well as by interpretive and postmodernist theorists who emphasize the social construction of reality and the reflexive and contextualized nature of knowledge. Among organizational scholars, Silverman (1970) employed an interpretive framework to argue that the dominant systems-based view of organizations needed to be replaced by an action-based account. He asserted that action analysis is particularly well suited to addressing neglected issues, such as the origins of organizations and organizational change. In a more programmatic statement, Burrell and Morgan (1979) distinguished between theoretical approaches stressing stability and order versus those emphasizing radical change. Their work stimulated efforts to advance interpretive and radical structuralist paradigms. Among theorists developing a more interpretive or cultural approach to organizations, a number emphasize the value of appropriating and adapting the tools developed by literary and humanistic scholars and suggest that society and its component units can be viewed and analyzed as 'texts' – that is, as a structure or grammar of rules and communication acts. Some propose the use of 'dramaturgic' approaches, focusing on the expressive dimension of social relations and the role of rituals and ceremonies in expressing commitments and dealing with social uncertainties. Others assert the value of 'narrative' analysis, which views organizations as ongoing conversations among interacting individuals involved in formulating and reformulating intentions, interpretations, and accounts to themselves and each other (Czarniawska, 1997).

Other relational scholars have emphasized not interpretive construction but rather network connections. *Network theorists* emphasize the value of viewing organizations as shifting networks of social relations embedded in fields of wider relational systems. Location or position in the network may be of greater significance in shaping an organization's behavior than its internal attributes. Both the organization's capacities and constraints on its action are determined by the ever-changing configuration of ties (and the lack thereof) among an organization and counteractors.

Network scholars have examined both networks within organizations and networks across organizations. Interorganizational networks can be created through a variety of connections: alliances; buyer–supplier relations; personnel flows; shared directors on the board; and even mere physical proximity, which can create informal connections (e.g., in Silicon Valley, where engineers from different companies and universities famously swap stories and ideas at shared watering holes). Network theorists have evolved an armory of methods and measures to examine the structure of social relations, and their insights have been absorbed into other areas of organizational scholarship For instance, institutional scholars have examined how the structure of social networks can channel the diffusion of innovations, often leading to field-level conformity in practices and structures. Other scholars have generated distinct insights on networks in themselves. Burt (1992) provided extensive theory and evidence showing that actors holding a position rich in structural holes (standing at the nexus of otherwise-unconnected clusters) often are presented with opportunities to act as a broker, innovator, or entrepreneur, bringing together ideas, people, and resources that otherwise might not have been connected. Podolny (2005) noted that networks are not just 'pipes' for channeling information and resources but also 'prisms' that reflect one's status: who you know matters, but who you are seen with sometimes matters even more.

The relational perspective has found allies in surprising places. Economists recognize that one of the most important features of an organization is its status as an independent legal entity. It is capable of entering into binding contracts in its own name, separate from those involving its individual participants. Parallel to the relational view of organizations in psychology and sociology, economists developed a view of the organization as a 'nexus of contracts': the firm as a 'focus for a complex process in which the conflicting objectives of individuals (some of whom may 'represent' other organizations) are brought into equilibrium within a framework of contractual relations' (Jensen and Meckling, 1976: p. 311). The stability of the equilibrium reached is a function of many factors, including changes in legal systems and contracting norms as well as the composition of and changing interests of participants.

Relational approaches celebrate process over structure – that is, becoming over being (cf Emirbayer, 1997). What is being processed varies greatly. In some versions, it is symbols and words; in others, relationships or contracts; in still others, assets. But in relational approaches, if structures exist it is because they continually are being created and recreated, and if the world has meaning, it is because actors are constructing and reconstructing intentions and accounts and, thereby, their own and others' identities.

Emergence of Organizations

Organizations are viewed as a construction of the modernist world, but there is much debate as to whether they represent accompaniments to and products of *industrialization* or, more

generally, vehicles of *rationalization*. From Adam Smith to Clark Kerr and Alfred Chandler, economists have viewed organizations as handmaidens to industrialization. The subdivision of tasks enables specialization and mechanization, but it usually is accompanied by agglomeration – the gathering of workers together in a common location – and requires coordination to integrate discrete tasks, typically through a command and control structure. A more recent but compatible conception advanced by *institutional economists* (Williamson, 1975), views organizations as operating to reduce transaction costs occasioned by the cognitive constraints (bounded rationality) of individual actors and the need to regulate opportunism among exchange partners. In either case, organizations are viewed as emerging to enhance efficiency: to reduce costs, whether of production or transactions.

Many of the most prevalent features of organizations – rules, formalized roles, dedicated machines, and established work routines – are intended to contribute to the reliability of performance. As often noted, however, these same mechanisms often prevent the organization from changing quickly enough to keep pace with environmental demands (Hannan and Freeman, 1989).

Sociological institutionalists argue that organizations should be viewed as a cultural construction: A product of increasing rationalization as generalized means-ends rules are promulgated and become valued independent of their contributions to heightened effectiveness and efficiency. The proliferation of organizations, and their infusion into virtually every arena of contemporary society, is viewed as resulting not only from their contribution to the coordination of differentiated, specialized tasks but also to their capacity to symbolize rational (rule-based, means-ends) procedures (Meyer and Rowan, 1977). The formal structure of organization, hierarchical controls, and the compilation of records all contribute to ensuring the accountability of organization performance and thereby enhance their legitimacy. These same structures, however, also are associated with red tape and ritualistic practices.

Viewed historically, organizations represent new types of social forms in that they are collective or corporate actors, accorded rights, capacities, and resources that are independent of those of any of its individual participants. Coleman (1974) employed changes in the law as important indicators of the growing independence and powers of organizations as they developed during the early modern epoch. Institutionalists such as Meyer, Dobbin, and Shenhav viewed the same process as being fueled primarily by the growth of a scientific ethos emerging during the Enlightenment that created abstract and general categories to classify and enumerate first the biological and physical universe and subsequently the social world. Local knowledge and culture, over time, succumbed to a new inductive epistemology viewed as universal. In the realm of purposive social organization, engineers and managers envisioned and then gradually helped to bring about the development of a single type of social entity (the 'organization') and a generic set of skills ('managerial') required for their maintenance. It is a vision that has been embraced and, hence, reinforced by the emergence of an academic discipline and profession devoted to the pursuit of organizational studies.

Levels of Analysis

The concept of organization is employed at various levels of analysis. More micro approaches treat organizations as distinctive types of social contexts that, in turn, affect the behavior and attitudes of their participants, whether considered as individuals or as groups or teams. Thus, the first level concentrates on organizational behavior. Viewed as social contexts, organizations generally are thought to be 'strong situations': Much effort and various techniques and devices are employed in an attempt to influence participant behavior. Positions typically are predefined, roles are prescribed, rules are formulated, authority relations are specified, information is routed selectively, specialized tools and equipment are provided, training is offered, incentives are created and sanctions are employed, and beliefs and values are inculcated. As Pfeffer (1997: p. 100) observed: "control is at once the essential problem of management and organization and the implicit focus of much of organization studies." Theorists differ in the relative priority they assign to different modes of control, whether economic, social, or cultural; but organizations are apt to combine many varieties of incentives and constraints in such a manner as to maximize the likelihood of compliance.

Moving up one level from a focus on organizational behavior, many analysts focus on the structural and other features of the organization qua organization. Here the organizational arrangements – extent of formalization, bureaucratization, centralization, mechanization, professionalization – instead of serving primarily as hallmarks of the setting become attributes of the corporate actor to be described and explained. Extensive comparative research has been conducted attempting to account for the widely varying features of organizational structure. Among the causal factors examined are the characteristics of the task and institutional (including cultural and political) environments, the demography of participants, and the life cycle of the organization.

When a particular organization is singled out and its context is described as it relates to this focal unit, an organization set level is being employed. This level was developed in association with the early stages of the open systems perspective and facilitates the examination of the particular information and resource flows and types of relations affecting the organization of interest. It is instructive to replace general descriptions of environmental variables, such as complexity and uncertainty, with specific information on who is providing what information and resources under what terms to the focal organization. This level of analysis has been particularly supportive of analysts employing *resource dependence*, *transaction cost*, and *strategic management approaches* (Pfeffer and Salancik, 1978; Thompson, 1967; Williamson, 1975).

The organizational population level is defined to identity and encompass all instances of a geographically bounded aggregation of all organizations of the same type. This level roughly parallels that of an *industry*, except that attention is limited to organizations of the same general type. The concern here is not the individual organization but rather the *organizational form*: variously defined as similar structures, a common blueprint or archetype, or distinctive constitutive information. Researchers working at this level examine the conditions under which new ways of organizing and new types of routines arise

and coalesce to constitute a recognizable, accepted form for the pursuit of specified goals. Analysts of populations examine the conditions under which populations of organizations emerge, grow, decline, and fail (Hannan and Freeman, 1989).

At the macro end of the scale, theorists have identified the organizational field as an important level linking individual organizations and organizational systems to wider, societal structures and processes. Organizational fields are defined as 'those organizations that, in the aggregate, constitute a recognized area of institutional life: key suppliers, resource and product consumers, regulatory agencies, and other organizations that produce similar services and products' (DiMaggio and Powell, 1983: p. 143). Fields are made up of multiple populations of organizations and their respective organization sets. Organizational fields vary greatly in terms of the extent of their organization and the degree of their structuration; and the emergence, development, and decline of organizational fields has become an important new focus of study.

Changing Theories; Changing Organizations

It would be odd indeed if there were no relation between our changing definitions and conceptions of organizations and changes in the phenomena itself. Over the past few centuries, organizations have evolved from relatively embedded and dependent components of traditional society to more independent systems that attempted to insulate themselves from the surrounding society, to systems that are much more open, more flexible, and more penetrated by their context. Since the beginning of the industrial period, organizations have developed from highly centralized to more decentralized structures; and they have tended to move from more tightly to more loosely coupled systems. Rather than having their component units be fixed jobs and departments, they increasingly are made up of more diffusely defined skill categories whose participants are grouped into changing configurations of teams and project groups. Also, jobs formerly linked densely in *internal labor markets* providing clear career lines to employees now more often are held by temporary workers or independent contractors whose mobility routes cross organizational boundaries. Rather than attempting to incorporate all functions within the same hierarchical ownership structure, organizations increasingly find ways to contract work out to relationally linked independent firms or to develop alliances with a shifting set of independent partners. New developments in information processing allow the collaboration of geographic remote partners and various combinations of off-site, part-time, and loosely linked participants. Ownership is no longer viewed as necessary – and in some situations is seen to undermine – control of essential resources and services.

Two master trends have shaped new understandings of organizations. First, globalization – the increasing interconnections in information, culture, and trade among the different countries of the world – make it clear that 'organizations' and our understanding of them are somewhat like breakfast. Although the first meal of the day might be labeled 'breakfast' everywhere, the actual content and size of that meal, and what is considered appropriate and sensible, varies wildly. In the United States, breakfast might consist of dry cereal and milk; in Switzerland, yogurt and muesli, in the United Kingdom, eggs, baked beans, and sausage; in Korea, kimchee, soup, and rice; in France, a croissant; in Argentina, steak. Appropriate beverages range from milk to tea to coffee to hard liquor. Similarly, organizations may share a designation, but surprisingly little else. Documenting diversity around the world has been a growth industry in the study of organizations.

Second, information and communication technologies – computers, telephony, and particularly the advent of the Internet – drastically have changed the feasible forms of organization around the world by vastly reducing the costs of coordination. The transaction cost profiles of different forms of collective action have changed radically, such that it now is possible to accomplish through dispersed horizontal groups feats that would have required formal hierarchies in prior times. Linux is now the world's most pervasive operating system, used on literally billions of electronic devices, and Wikipedia is the world's most widely used encyclopedia (and an indispensible tool for students everywhere); both were created via open-source communities consisting of tens of thousands of individuals who have never met – a format that fits our definitions of 'organization' only problematically. 'Organizing' has surpassed 'organization' in field after field (Scott and Davis, 2007).

We thus are left with a paradox: On the one hand, we seem to live in a society of organizations in which nearly every aspect of our lives occurs in and through formal organizations, including birth and other vital events, education, politics, economic mobility, and even family life itself, as more of what we do on a daily basis, from cooking food to changing the oil to tutoring our children can be contracted out to suppliers (cf Perrow, 1991). On the other hand, societies around the world have become so rationalized that the order formerly created within organizations increasingly is embedded in society itself (Meyer, 1983). The largest corporations increasingly are evanescent, relying on networks of contractors and fictional legal devices around the world to design, produce, and distribute their products. The functions of organization increasingly are available off the shelf to entrepreneurs who snap them together and take them apart like interlocking plastic toys that increasingly resemble the 'nexus of contracts' described by economists (Davis, 2009). The twenty-first century already has shown that organizing will continue to demand new strategies for understanding.

Abstract

Organizational behavior (OB) denotes a relatively new area of research and practice of psychology. It refers to the study of both the psychological and social antecedents and consequences of behavior of individuals and groups in organizations, as well as the psychological and social antecedents and consequences of the behavior of organizations. Stressing a psychological point of view, this article defines the field of OB and describes the main characteristics of its dominant domains, their methodological implications, and the likely future directions of OB.

Organizational behavior (OB) denotes a relatively new area of research and practice of psychology. It refers to the study of both the psychological and social antecedents and consequences of behavior of individuals and groups *in* organizations, as well as the psychological and social antecedents and consequences of the behavior *of* organizations. Stressing a psychological point of view, this article defines the field of OB and describes the main characteristics of its dominant domains, their methodological implications, and the likely future directions of OB.

The Nature of the Field

As in any new scientific field, various attempts have been made by different authors to define the field of OB. In the very first review entitled 'Organizational Behavior' in the *Annual Review of Psychology*, Mitchell (1979: p. 244) considers OB as a "distinct discipline with a focus on individual and group behavior in the organizational context," thus making it virtually synonymous with traditional work and organizational psychology. Staw (1984: p. 628) underlines the interdisciplinary character and the two main orientations of the field, the stress on micro- and macroissues: "organizational behavior is an interdisciplinary field that examines the behavior of individuals within organizational settings as well as the structure and behavior of organizations themselves." According to this view, microaspects are dealt with by psychology whereas macroaspects are treated by sociology, political science, and economics, making OB appear as two distinct subdisciplines, an impression that is further fostered by different professional identifications of the students of OB. Others simply define OB operationally in terms of the organizational research topics and issues published over time in scientific psychological periodicals (Rousseau, 1997) covering, for instance, leadership, motivation, organizational technology, job analysis, legal issues, and organizational performance.

A more integrative stance is taken by Schneider (1985: p. 574) in focusing on the types of studies conducted in OB: "OB is the confluence of individual, group, and organizational studies flowing from industrial–organizational (I/O) psychology and organizational and management theory (OMT) with headwaters in psychology (social, psychometrics), sociology (organizational, work, and occupational), and management (scientific, human relations)." Given this mixed heritage of OB, its scope is extremely broad, covering both micro- and macrophenomena of organizations. McGrath (1976), in an early, even more comprehensive manner, conceptualizes OB as the intersecting area of three systems: the physical–technical/structural, the social–interpersonal, and the person system of organization members.

From a psychological point of view, OB may thus be defined as an emergent field of scientific inquiry, which is constituted by the converging contributions of various social and behavioral sciences focusing on multilevel and multidimensional antecedents and consequences of psychological phenomena in organizations. The multilevel perspective of OB implies that literally *all relevant levels and dimensions* that either condition or are conditioned by psychological phenomena in organized settings fall into the scope of OB studies: the levels of the individual–personal, the group, the managerial, the technological, the organizational–structural, the interorganizational, and environmental. The notion of multiple dimensions refers here to organizational practices, processes, and outcomes of any of the relevant system levels as proper problems of OB studies.

Although the study (Greve, 2013) of organizational issues has been part and parcel throughout the history of work and organizational psychology (Münsterberg, 1912), it remains a moot question why it was only during the last three decades of the twentieth century that OB entered the scene as a distinct subfield of scientific inquiry. One may hypothesize that factors seem to have interacted here that are partly due to change in society and partly due to intrinsic developments of science, both of which made their effects particularly felt in the decades after World War II. Epochal shifts in the work force such as the growth of the service sector of economy, the demographic changes in terms of age and gender composition implied drastic restructuring of vocational and professional profiles. The cost-effective wholesale introduction of new information and communication technologies in work settings created

[†] Deceased.

dramatic challenges to a novel division of labor. Social value changes such as the changing subjective meaning of working (MOW, 1987) and the increase of international market competition may have further been contributing factors of societal change to highlight the need for the reform of work organizations and social institutions that had to go far beyond a restructuring of individual work places. Required were more holistic approaches to the study and practice of organizational change and performance that eschewed monodisciplinary psychological treatments. This is where progress in science offered itself as a promising solution. The emergence of systems theory as a metatheoretical intellectual vehicle to facilitate multilevel studies and to link different scientific disciplines to each other in the analysis of complex scientific and practical problems appears to have been a further necessary condition for OB to acquire scientific credibility as an interdisciplinary field.

Despite its comparatively short history, OB is far from displaying a unified common theoretical framework and a corresponding set of issues under study. The most important theoretical underpinnings and the substantive problems studied in their perspective will be addressed next. These theoretical perspectives represent umbrella orientations usually encompassing diverse theoretical positions of varying scope, which depending on one's meta-theoretical penchant, may also be classified differently.

Theoretical Paradigms and Topical Foci

Psychology of Individual Differences

The basic tenet of differential psychology within OB is the assumption that personal characteristics constitute the core of variables to be studied by psychology either as causal (at least moderating) factors of consequent psychological/social phenomena or as the most important outcomes of individual experience in organizational settings. The micro-perspective dominates here. Within this theory class might also be counted the important approaches of expectancy and of goal setting theory in as much as individual characteristics (e.g., preferences, competencies) need to be considered by them. The former surmises that subjectively expected outcome values (subjective expected utilities (SEU)) guide individual decision-making behavior (Naylor et al., 1980), the latter postulates that goals, self-set individually or interactively by subordinates and superordinates, constitute potent predictors of subsequent behavior in organizations.

Major topical concerns within this paradigm concentrate on issues such as the role of personality and leadership style as conditioning work group and organizational performance (including absenteeism from work, turnover), work attitudes (causes and consequences of job satisfaction, meaning of working, and work commitment/motivation).

Bureaucratic Theory

An important contribution to the advancement of OB was made by the interdisciplinary team of Aston University (Birmingham, UK) under the leadership of a psychologist, Derek Pugh (Pugh and Hickson, 1976). Taking Max Weber's theory of bureaucracy as the starting point, the Aston group deviated from the received single-level analytic procedure and proposed to overcome this by integrating the analysis of three levels: situational factors (size of organization, technology, environment), organizational structure (decision centralization, specialization, formalization, configuration), and member experience and behavior. A basic assumption was that cross-level effects had to be taken into account in the sense that an organization's technology would impact the division of labor, i.e., the role structure of the organization which, in turn, would influence autonomy and individual outcomes such as the evaluation of one's work setting (motivation, commitment, satisfaction). Thus the Aston approach covers both micro- and macro-dimensions of OB.

As a major achievement of the Aston group, apart from introducing from its outset a theoretical multilevel and interdisciplinary perspective must be considered its success in setting current psychometric standards for the development of instruments for an adequate analysis of organization structure and its interaction with variables on other system levels. A burgeoning body of studies followed from their lead.

Cognitive Psychology

The generally noted 'cognitive shift' in psychology during the latter part of the twentieth century soon was also to reach OB and to influence paradigmatic thinking in the field. Cognitive processes are in this perspective considered to mediate or govern behavior. Various positions fall under the umbrella category of cognitive psychology, some of which achieved prominence in OB; the three most important ones are social cognition, expectancy theory, and attribution theory (Hodgkinson, 2003).

Social cognition refers to processes among relevant actors, which produce socially shared representations, views, and perceptions of organizational realities. Thus some 'social constructivist' authors claim that organizational phenomena are mainly socially constructed and articulated through negotiated goals, structures, artifacts, through myths, rituals, stories, and symbols, which result in organization-specific, intersubjectively shared meanings and values (Turner, 1990). Social constructivism favors an ethno-methodological and anthropological, holistic approach to organizations, which lends itself to the analysis of molar organizational features such as organizational culture and climate. Under the heading of social cognition must also be mentioned the significant contribution of equity theory, which focuses on an actor's input–output ratio in comparison with the respective ratio of similar others with the resulting energy expenditure and work satisfaction. *Expectancy theory*, as described above, addresses the cognitive processes of organization members' choices according to perceived SEU. It has shown considerable fruitfulness in the study of leadership, self-efficacy, and work motivation. *Attribution theory*, owing to its focus on perceptual processes concerning perceived causes of success and failure, has to a large extent influenced theorizing and empirical research on

achievement motivation and respective performance in organizations.

Action Theory

Many different theoretical social and behavioral science approaches go under the guise of 'action theory.' Some of them play a major role in OB. A large body of German theoretical and empirical literature under the name of action control/regulation theory needs to be subsumed here (Frese and Zapf, 1994). It combines elements of cybernetics and cognitive aspects of goal-oriented behavior (actions) that is assumed to be regulated by feedback loops concerning the deviations from goal achievement, which necessarily includes the consideration of task and technical components of task and organization structures. The approach has proven its usefulness in a wide variety of domains, e.g., human error analysis, personality and competence development, individual task and organization design, linking socially shared meanings, and values to collective action control.

A notable French approach of sociological provenance (Crozier and Friedberg, 1977) puts social actors (individuals, groups, organizations) and their various strategies of playing their power games into the center of its theoretical and empirical analysis. In this context, games are not understood in a metaphoric sense, but as concrete mechanisms to structure organizational power relations among interdependent actors negotiating degrees of freedom within given organizational and environmental constraints and opportunities. Games are here considered as the very instruments that regulate and sustain stability and integration of organized behavior based on accepted rules of the games. Thus the authors succeed in encompassing both micro- and macroaspects of OB.

The notion of autopoiesis, derived from biology (Maturana et al., 1980), has attracted growing interest also in OB. The concept refers to the continuous and structurally coupled adjustment of living systems to their extant environment and their continuous systemic self-reproduction. It has been applied to, among others, self-organizing capacities of institutions of public administration and their sustained regeneration of the bureaucracy and the autonomy and self-governance of organizations acting in the public area. The link of micro- and macroaspects of organizations in their given environment becomes clearly dominant in this perspective.

Systems Thinking

A lasting paradigmatic contribution to OB was made by the so-called socio-technical systems approach (STSA), developed soon after World War II by a group of social scientists of the London-based Tavistock Institute of Human Relations (Emery and Trist, 1960). The approach grew out of general systems theory and is predicated on important assumptions concerning the interaction of an organization's *social* subsystem (its members, role structure) and its *technical* subsystem (task structure, technology). In linking task and technological elements to the social patterns of organization, STSA paved the ground for systematic analysis and design of work places and work organizations. Work and organizational design was postulated to proceed always through joint optimization of both subsystems in order to guarantee efficiency. The increased participation of employees in organizational change programs became a leading principle. Thus, it was possible to take into account both the characteristics of organization members (their values, aspirations, expectations, social and hierarchical relations, role ascriptions, etc.) and the organization's technical dimensions.

The theoretical innovations of the STSA proved to be of great practical usefulness in providing guidelines for the design of work and work organizations which met, for instance, the demands of differential levels of human competencies and also of technical and task demands. The large majority of work humanization programs of the 1970s and 1980s profited from them in many industrialized countries. It facilitated improvements in the adequate introduction of new information and communication technologies, the creation of flexible production units, the formation of semiautonomous work groups, and the creation of large-scale industrial democracy schemes.

Unresolved Issues and Future Directions of OB

The multilevel perspective of OB poses an intriguing *theoretical problem*: How can and should the relationships of several system levels be conceptualized? One case in point is problems such as the structural interrelations of organization-specific features (organization strategy and structure, membership resources, organizational practices, output) and characteristics of their institutional and societal environment (dominant culture, education and legal system, economic and technological status). While there is growing evidence that these features are interrelated and influence each other, theoretical integration remains lacking. A possibly promising theoretical solution might be found in Giddens' theory of structuration. Giddens (1984) postulates a dual nature of institutions recursively reconstituting and maintaining each other. On the one hand, institutions, by virtue of their existence, facilitate action of individuals and of organizations, and on the other hand, by virtue of the acting actors, the institutions are recursively constituted and sustained. The theory still being on a rather abstract level requires further development in order to make it fruitful in OB.

A *methodological problem* of considerable difficulty is the need to account for effects of time. Change and continuity of organizations may be likened to quasistationary equilibria (Lewin, 1952). Like rivers they are in continual flux while preserving their identity and basic characteristics for some time. One methodological response of OB to study change and continuity was to repeat several cross-sectional studies at various points in time, thus approaching some sort of longitudinal evaluation. Another response was to trace organizational developments historically through document analysis and interviewing. Yet another approach seems to be to employ more 'dense' descriptions of organizational processes over time by way of ethnographic participant observation. This is a choice that is increasingly advocated and implemented by many researchers in spite of its cost, simply because of its superior information yield.

Finally, it may be that at the turn of the millennium, *societal changes* as alluded to above will gather further momentum to

induce also a new organizational era impacting on OB. According to Rousseau (1997), organizations seem to be faced with the challenge of increasing upheaval and transition of depth and magnitude that were hitherto unknown. She refers to governmental measures of deregulation, global competition, the explosion of information technology in manufacturing and service sectors, the uncoupling of traditional education from work demands, the emergence of small-firm employment, new and more differentiated employment relations, outsourcing among firms and interorganizational networking, shifts from managerial prerogatives to self-management, transition from rule-regulated work to self-reliance, and continuous adaptation of workers. In short, traditional internal organizational structures are becoming more fluid and the boundaries of organizations blurred. The perceived meaning of organization as a clear-cut entity seems in need of change to adaptive *organizing*. A reorientation of OB with reference to thematic foci in addition to theoretical underpinnings would have to be the consequence of such developments. Theoretically, a renewed emphasis on the conceptualization of the dynamics of organizational and interorganizational processes is called for. New topical issues are likely and desirable to emerge as concern for OB, such as the changing nature of employment and equitable forms of remuneration (Scott and Davis, 2007), emergence of multiple loyalties, individual learning for self-management and career development, organizational learning, and intervention methods to introduce and to sustain change. OB seems to be facing new and wide areas to be examined, a task for which its intrinsic multilevel and interdisciplinary outlook will be a definite asset.

Comprehensive treatments of the field can be found in the following publications: *Handbook of Industrial and Organizational Psychology*, vols. 1–4 (see Frese and Zapf, 1994); *Annual Review of Psychology; International Reviews of I/O Psychology; Administrative Science Quarterly; Organizational Studies; Human Relations;* and *Journal of Occupational and Organizational Psychology*.

Organizational Citizenship Behavior

Dennis W Organ, Bloomington, IN, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Organizational citizenship behavior (OCB) refers to discretionary, nonrequired contributions by members to the organizations that employ them. Evidence indicates that job satisfaction is more closely related to such contributions than to productivity in core job tasks. Other data suggest that personality also is more likely to predict such discretionary behaviors rather than task productivity. Various typologies and dimensions of OCB have been posited, but the most parsimonious structure consists of two major dimensions, roughly analogous to discretionary help and support to particular persons and discretionary levels of conformity to organizational rules. Compelling findings support the hypothesis that unit level OCB indeed predicts various criteria of organizational effectiveness. Cross-cultural research in OCB has begun and is proceeding at an accelerating pace, with indications that the structure of what is perceived as OCB varies somewhat across cultures. Moreover, some forms or levels of intended OCB might prove dysfunctional for either the organization or the individual or both.

The Construct and Its Boundaries

Organizational citizenship behavior (OCB) pertains to discretionary behavioral contributions that members (e.g., employees) render to their organizations. The qualifier 'discretionary' conveys the notion that such behavior is either not part of the job description or is a dimension of the job requirements that cannot be easily quantified (e.g., 'cooperates with colleagues') or enforced beyond some minimal level (such as attendance or punctuality). Some examples of specific OCB are helping a new hire 'learn the ropes', exemplary attendance, making timely suggestions to the appropriate parties and in an appropriate forum for more efficient operations, acting to prevent or resolve conflicts between or among colleagues, or spontaneously helping a coworker with some problem or urgent task. In sum, OCB subsumes those actions generally desired by organization leaders but often not easy to define operationally with respect to time, place, and amount.

Furthermore, because OCB is seldom easily quantified or monitored, it does not lend itself to incentive systems in the manner of, for example, physical output or sales revenues. This is not to say that abundant OCB on the part of an employee could not or would not be recognized and rewarded in some fashion, such as a later increase in wages or salary, recommendation for promotion, or informal favored treatment by a supervisor. But such rewards would more typically arise from reputational effects that foster holistic impressions among colleagues, and possibly superiors, based on numerous brief, specific episodes in which OCB was exhibited and later recalled by various other parties. In other words, OCB is rewarded on the basis of the extent to which specific behaviors lead to a general impression, which in turn might or might not lead to recompense.

Theoretical Roots

Perhaps the earliest articulation of something evocative of OCB came from Chester Barnard (1938). His basic notion of organization was what he called a 'cooperative system'. He described as 'indispensable' the 'willingness of persons to contribute efforts' to such a system. For him, this 'willingness' captured the more common terms of solidarity, *esprit de corps*, or loyalty. He added that such "willingness" was "…something different from effectiveness, ability, or value of personal contributions…." (Barnard, 1938: p. 84)

Roethlisberger and Dickson (1939), in their pioneering account of the famed Hawthorne studies of the 1920s and 1930s, noted that an 'informal organization' is part of every organization and described it as a 'necessary condition for effective collaboration' (Roethlisberger and Dickson, 1939: p. 562). In other words, much of what makes an organization effective comes from spontaneous and informal exchanges of help, information, and support.

From Katz and Kahn (1966, 1978) came a more precisely articulated version of such collaboration, close to what is now often referred to as OCB. Their analysis posited three forms of behavior that organizations must evoke in order to function: (1) attract and hold people in the system; (2) ensure that members exhibit reliable in-role performance, i.e., do the assigned jobs for which they were recruited and trained and which largely determines base compensation; and (3) encourage spontaneous behavior beyond role or job prescriptions when such behavior is needed. Katz and Kahn elaborated upon this third requirement to say that it includes cooperative interactions with coworkers and colleagues, suggestions for improvement and solving problems, actions protective of the system, and promoting a favorable image of the organization in the external environment.

Current Conceptions

Organ (1977), in an essay on the sparse evidence supporting the 'satisfaction causes productivity' hypothesis, suggested that job satisfaction is likely to be more closely related to OCB – that is, the ongoing stream of what Barnard described as 'willingness to contribute', Roethlisberger and Dickson referred to as 'collaboration', and Katz and Kahn called 'spontaneous' gestures of cooperation, supportiveness, and protection. Organ

reasoned that objective, quantifiable individual productivity is more typically a function of skill, training, technology, and in some instances the explicit contractual incentives attached to objective individual performance. Job satisfaction – as a prototype attitude about the organization, its supportiveness and fairness of treatment – is more likely to affect those behaviors that are not constrained (e.g., by the technology of the job functions in which the individual is involved or the individual's level of relevant technical expertise), nor governed by compelling extrinsic incentives or penalties. Thus, Organ's (1977) interest in OCB arose from the effort to identify the behavioral manifestations of positive attitudes about the job environment. Initially, the focus was on general job satisfaction, but eventually included beliefs about fairness, particularly perceived fairness of pay, benefits and supervisory treatment.

A meta-analysis (Organ and Ryan, 1995) of 28 studies found a weighted average raw correlation of 0.24 between satisfaction and OCB, with a 95% confidence interval of 0.20–0.27. An earlier review of satisfaction and overall job performance (Iaffaldano and Muchinsky, 1985) had reported a 95% confidence interval of 0.13–0.17. Thus, there seemed to be some empirical support for the belief that job satisfaction and related positive attitudes are more likely to have their effect on OCB rather than productivity or overall performance.

What Constitutes OCB?

The original conception of OCB was holistic and not broken down into components. That is, early studies cobbled together a list of behaviors that seemed to share the underlying idea of 'doing something good that is not part of strict job definition and does not qualify for guaranteed reward'. Thus, items were designed that referred to helping others, living up to the spirit as well as the letter of the rules, above average attendance and punctuality, not complaining about temporary inconveniences, interpersonal courtesies that help prevent problems for others, acting to defuse interpersonal conflicts, and taking part in discussions in a constructive, proactive fashion. However, factor analysis of the OCB measure in an early study (Smith et al., 1983) revealed two distinct underlying factors: interpersonal OCB (OCB-I) and organizational OCB (OCB-O). The distinction between the two factors had to do with the *target* of the behavior, that is, whether the focus was a specific individual or individuals vs the more general or collective formal organization. Thus, helping, courtesy, and peacemaking benefit one or more specific individuals, typically part of the work group, while exemplary rule compliance and speaking up in meetings usually are directed toward the larger organizational collective. Across various studies using different measures of OCB, this two-factor structure remains the most reliable and robust, and probably most parsimonious, representation of the larger construct.

Contextual Performance

Borman (1983, 1987) offered a construct that has much in common with OCB on its most substantive or operational level. However, he defined it in terms of the contributions pertaining to the *context* within which core task performance of the group occurs. In particular, his emphasis was on the psychological and social context that supports and facilitates performance by the group as a whole. The specific items in the measure of contextual performance (CP) overlap considerably with OCB measures in referring to such contributions as helping others, making constructive suggestions, providing a model of self-discipline, and loyalty to the organization (e.g., representing it positively to outsiders). Moreover, measures of CP typically break down into two factors – interpersonal facilitation and job dedication – that bear much resemblance to the OCB-I and OCB-O factors in OCB measures.

However, Borman's scheme does not rule out some expectation of reward, nor does it require that the behavior in question lie outside the scope of the job or role definition.

Furthermore, whereas OCB was formulated as a means of defining the types of positive contributions that were more likely to be a function of job satisfaction, Borman was interested in the important work behaviors more likely than individual task performance to reflect the importance of personality dimensions. However, his rationale was much like that of Organ (1988). Personality, like attitude, predicts behavior much better in 'soft' than 'hard' situations. Soft situations are those in which no particular behavior is forced (by law, custom, compelling rewards or punishments), i.e., where there is discretion. Borman, not discouraged by the disappointing results in trying to link personality to job performance or productivity, reasoned that productivity is constrained by skill differences, technologies, and the salience of compelling rewards or sanctions. He viewed CP as the domain in which differences in personality would have their major effects.

Some evidence does support the proposition that certain personality dimensions more consistently predict CP than hard measures of productivity. The evidence comes mainly from studies using the 'Big Five' conceptions of personality (McCrae and Costa, 1987): agreeableness, conscientiousness, extraversion, neuroticism, and openness to experience. In particular, the dimension 'agreeableness' has some empirical connection to interpersonal facilitation, while 'conscientiousness' more reliably predicts task dedication.

On the other hand, Organ and Ryan's (1995) meta-analysis found less support for a relationship between personality dimensions and either holistic OCB or particular dimensions of it, particularly when looking only at studies that used something other than a self-report of OCB (i.e., a supervisory or coworker rating rather than the respondent's own self-rating). The only personality–OCB connection that stood up to conventional standards of statistical reliability was the correlation between the Big Five's measure of conscientiousness and OCB-O (more impersonal OCB).

Still, it seems intuitively compelling that some dispositional factors would logically pertain to most forms of OCB. Perhaps a better test of this belief would take the form of observer ratings of subject personality and a supervisory rating of OCB. Mount et al. (1994) used such a design, with customer, coworker, and supervisor as procedurally independent ratings of personality, CP, and in-role performance. When different variables were matched up with different sources, the correlations between personality and CP were noticeably stronger than were typically found in prior research.

OCB and Organizational Effectiveness

The presumption at the outset of work on OCB was that the sorts of behaviors defined by the concept operationalizing it would have something to do with how well organizations function. The actual items that comprise measures of OCB sound much like what we would assume to be the profile of a healthy, efficient enterprise. Indeed, even to suggest that such behaviors make organizations function better could be considered a truism.

However, the tautology resemblance is less troubling if we at least surmise *why or how* such behaviors benefit the larger collective. Organ et al. (2006) have articulated some reasoning along such lines. First, some forms of OCB represent *added resources*. For example, someone who takes the time to help a new hire learn some operations is providing additional inputs to those not otherwise forthcoming in the mix of organizational resources. Second, OCB serves to economize on the use of resources already at the organization's disposal. This might be illustrated by the staff member who steps into the breach to resolve conflict or prevent conflict from taking its toll on the stamina of colleagues or draining the time and energy of managers who have to become referees. Similarly, timely suggestions in the appropriate tone and forum often provide the means of reducing waste of materials, money, and time. Finally, as we will see below, a transactional analysis of organizations (Williamson, 1975) argues that the very reason for the existence of organizations is that they minimize the extent and cost of transactions needed to negotiate or contract for the inputs they require. Absent OCB, much effort would be diverted into ascertaining what benefits would derive from each and every efficacious input.

Ultimately, though, the tautology problem can be dealt with only by empirical research that takes OCB to the macro level. We must show that in organizations or portions of organizations where more OCB occurs, the more effective they are judged to be in terms of some specified criteria.

However, doing this is not an easy task. Such research requires a group of organizations, a group large enough to have at least minimally adequate statistical power. Furthermore, each organizational unit within that group must lend itself to at least one objective criterion of effectiveness, preferably more such criteria.

One approach to dealing with this problem takes the form of studying small but semiautonomous units of chain-type organizations, as are found in retail firms and restaurants. Walz and Niehoff (2000) used this strategy with a chain of 30 limited-menu restaurants and found significant positive relationships between the OCB dimension of helping behavior and the measured criteria of operating efficiency, customer satisfaction, and an index of quality of performance. Koys (2001) followed a similar research strategy, but with a longitudinal design, in order to determine if earlier OCB predicted later effectiveness better than the converse (prior effectiveness predicting subsequent OCB). The results favored an inference in which OCB was the prior predictor or cause, as opposed to representing the effect of prior effectiveness.

Subsequently, Podsakoff et al. (2009) conducted a meta-analysis of 38 studies that investigated OCB and organization-level outcomes, with varied criteria, such as productivity, reduced costs, and customer satisfaction. The estimated population correlations between unit level OCB and 'positive' criteria ranged from 0.15 (for unit profitability) to 0.47 for subjective or reputational measures of effectiveness. For 'negative' criteria (staff turnover and operating costs), the correlations were negative, i.e., higher unit level OCB was associated with lower turnover and costs. The authors also noted that time-lagged correlations between earlier OCB and later outcomes were generally stronger than those associated with same-time measures.

OCB and Individual Outcomes

We noted earlier that OCB was conceived as discretionary behavioral contributions. 'Discretionary' implies the absence of any guaranteed or contractual reward for such behaviors, as well as the absence of any expected sanction for not displaying those behaviors. Moreover, while some such behaviors might fit within a general statement of certain expectations in a job description – such as 'cooperative', 'courteous', 'self-disciplined', or 'reliable' – seldom are such expectations defined in operational terms. On the other hand, an organization often does cite behaviors, such as deliberately falsifying documents, insubordination, physical or verbal abuse of others, that are subject to punishment or discharge. Positive actions that might be specified as qualifying for remuneration could include productivity (especially in sales jobs but also in others that lend themselves to objectively quantifiable individual output), attendance, and remaining in the organization in good standing. In between those extremes are many small positive or negative behaviors that can easily escape notice, are not quantifiable, and ultimately are matters of reputation within the work group, from customer feedback, or sometimes noted by officials in other departments. Some people practice more, others less, of these behaviors. Reputations based on such 'microcontributions' usually lag behind their rendering by days, weeks, months, or more.

What we do find, however, is that reputations for doing these things do often meet with positive outcomes. The Podsakoff et al. (2009) meta-analysis cited above found abundant and conclusive evidence that OCB does often redound to the individual's benefit. Overall, characteristic OCB is associated with more positive performance evaluations (by peers as well as supervisors and higher level management), recommendations for promotion, and in general with more favorable treatment in terms of the social exchange process between individuals and their supervisors.

OCB and the Cultural Matrix

Early research on OCB was almost wholly confined to USA settings. Therefore, the theory and research were predicated on the thinking about how OCB would be manifested in American organizations.

In recent years, empirical research in industrial and organizational psychology in other countries has increased significantly, and by the 1990s scholars had raised questions about the degree to which OCB research in the USA, or even the very

idea of what OCB meant, could be generalized to other cultures. For example, the US is generally agreed to exhibit a quite individualistic culture and, not surprisingly, OCB is regarded as something an individual chooses to contribute or not contribute. In more collectivist cultures, this concept might not fit as well; rather, there are likely to be strong and shared norms about work behavior, such that members should do certain things and not do others, regardless of what some individuals might prefer to do or not do. In cultures characterized by well-defined levels of power, doing what is 'discretionary', i.e., beyond one's instructions, carries some risk, as it might be resented by the boss.

A study by Farh et al. (2004) gave Chinese respondents a general definition of OCB and asked them to describe examples from their experiences and observations at work, producing 756 distinct examples that they thought exemplified OCB. Content analysis of these produced 10 distinct dimensions. One of those was 'helping', at first glance similar to what obtains in US samples. However, the Chinese interpretation of 'helping' as OCB went well beyond the workplace. It was considered OCB if someone helped the family member of a coworker, or helped with work on a colleague's house. 'Harmony' was a separate brand of OCB, indicating a major ongoing concern with avoiding conflict in the workplace. In state-owned firms, OCB included a factor that pertained to volunteer work in the community. Another factor that emerged was self-training – on one's own, learning more skills that could be applied at work.

If the conceptual structure of OCB varies across national or regional cultures, one might well ask whether different industries and occupations – which plausibly generate differences in organizational culture – might also have different conceptions about OCB. Health care organizations, research laboratories, advertising, correctional facilities, arts organizations are just few that come readily to mind, with varied ideas as to what best fits important categories of OCB. Thus, one daunting challenge in the community of OCB theorists and researchers is to figure out what level of breadth vs specificity will prove most efficacious in future work in this area.

Is There a 'Dark Side' to OCB?

While we have reported here a fair amount of evidence that OCB at the macro or collective level does predict reasonably well a number of criteria of organizational effectiveness and often generates positive outcomes for members who exhibit more of it, some concern has also been expressed about the 'down side' of OCB. One such concern is what it does to the health, home life, and 'burnout' of those who expend enormous amounts of time and energy doing things that go beyond what the job requires. Others worry about the toll that OCB might take on some individuals' performance of their major job-related tasks. Some have suggested that a potentially large portion of OCB is performed as part of a calculated strategy of ingratiating supervisors and higher levels of management (Bolino, 1999). Others have suggested that some forms of OCB might be unethical or even illegal – i.e., doing something regarded as 'good' for the organization but 'wrong' in other, broader respects, possibly unethical or even illegal.

No doubt all of us could summon from memory some people who seriously overloaded themselves with OCB, possibly leading to health breakdowns; individuals who involved themselves so much in doing extraneous tasks that they neglected their core formal responsibilities; quite a few that seemed to curry favor with important people by appearing always to go the extra mile.

In answer to some of these concerns, some would point out that meta-analyses indicate that OCB not only does not negatively correlate with of core job performance, but is either essentially unrelated to in-role productivity (when different sources are used for the two types of contributions) or substantially positive (when the same source rates both factors; Organ et al., 2006). Furthermore, a means of discerning whether and to what extent OCB arises from an attempt to manage impressions of others, is to use multiple sources of rating. Peers and lower-level members would not likely be misled by apparent OCB that is exhibited only for the benefit of the boss.

Furthermore, to have concern about OCB because it might represent a tool of ingratiation seems to suggest that OCB should have the right motive, otherwise it is a negative form of behavior. Such a stance would denigrate a wealthy donor's large contribution to a charitable organization if the motivation – or even part of the motivation – were to involve building a good reputation in the community. One is hard-pressed to argue that the dollars in the donation do any less good for the recipient. In any event, OCB is not defined by its underlying motive. Arguably a complex of varied motives underlies much behavior at work. To date, the most straightforward conjecture about a dominant motive for OCB comes from social exchange theory (Blau, 1964), i.e., people will try to reciprocate good treatment by someone with comparably treatment to that person – or organization. If the individual has reason to perceive the organization as a microcosm of 'a just world', one in which the long-run dynamic is toward fairness, then that individual will not stint in discretionary contributions.

As for the concern that excessive OCB, piled upon diligent care to perform one's core job well, might cause health breakdowns or domestic problems, we have no data at hand to document the frequency or severity of this potential problem. We find it plausible that such cases exist. But we find equally plausible that some people have overextended themselves within the core functions of the job, regardless of how much or how little OCB added to it.

Current Trends and Future Tasks

A major trend in recent years is the status of OCB as a criterion or dependent variable in organizational research. Research designs that once studied such factors as pay systems, leader behavior, organization design, and personality, as they related to job satisfaction and productivity, now often include a measure of OCB or CP. The range of industries and organizational types in which is studied continues to increase. Also, there is anecdotal evidence that some management practitioners now attempt to give more weight to OCB in overall evaluations of employees and that they now search actively for some means of predicting it in the personnel selection system.

However, one would hope that organizational psychologists will continue to work toward more conceptual clarity in the OCB concept, the optimum level of generality vs specificity, and measurement tools that yield the best return in value-added decision-making for the cost of including it in the management information system. There must also be some reckoning with what might the limits of application of OCB concepts, i.e., contexts in which it informs neither theory nor practice.

Abstract

This article examines the concept of organizational climate and its metaphorical derivation. It begins by defining what is meant by the construct and the specific conceptual challenges that researchers face in trying to agree upon a single definition. Different statistical functions of organizational climate scores which have recently emerged in the literature are outlined using examples from relevant research findings. Empirical research into global and facet-specific organizational climate is then described. Given the plethora of facet-specific climate studies which have emerged in the literature over the past decade, the article concludes with a call for a more unified theoretical and methodological approach when conducting future research on organizational climate.

Defining Organizational Climate

For many years, management scholars have grappled with the challenge of understanding how organizational context impacts and shapes the attitudes and behavior of organizational members. Much of this endeavor has centered on the construct of organizational climate. Climate has been variously described as "the way things are around here" (Schneider, 1990) to "a molar concept reflecting the content and strengths of the prevalent norms, attitudes, behaviors, and feelings of the members of the social system which can be operationally measured through the perceptions of system members, or observational means" (Payne, 1990: p. 156). The *Oxford English Dictionary* defines meteorological climate as "the prevailing atmospheric phenomena and conditions of temperature, humidity, wind, etc., of a country or region." When applied to communities, climate is "the mental, moral, etc., environment prevailing in a body of people in respect of opinion, some aspect of life, etc." Thus, just as we describe climates in terms of sunshine, prevailing winds, levels of rainfall, etc., organizations are described in terms of dimensions such as leadership style (autocratic versus democratic), concern with the well-being of employees, emphasis on productivity, formalization or bureaucracy, innovation versus traditionalism, and commitment to quality in service or production.

Although there is a general consensus around what organizational climate means, trying to agree upon a specific definition in the literature remains a challenging task, once described as like trying to "nail Jell-O to the wall" (Schneider, 1990: p. 1). Questions which create difficulties for researchers include: Are climate phenomenon perceptual in nature, or do their capture objective attributes of an organization? How does the concept organizational climate differ from organization culture? And at which level of analysis should organization climate be measured? This has led copious climate definitions in the literature. However, for the purposes of this article, we adopt the widely accepted conceptualization proposed by Schneider and Reichers (1983), which defines organization climate as a set of shared perceptions about the practices, procedures, and policies that an organization expects, supports, and rewards. Organizational climate captures the aggregation of individual psychological meanings of their work environment and is therefore a collective perceptual phenomenon (Kuenzi and Schminke, 2009). Research on organizational climate explores how individual perceptions regarding their workplace impact both individual outcomes (such as job satisfaction, individual performance, and organizational citizenship behavior (OCB)) both group and organizational outcomes (such as team performance and customer satisfaction). As shall be examined later in this article, empirical studies are therefore increasingly conducted at multiple levels of analysis to understand more about how individuals, groups, and organizations interact.

Another continuing debate in the literature concerns the demarcation of organizational climate from organizational culture. Schneider and Reichers's (1983) definition establishes that climate, although related, is distinct from culture. Indeed, both of these concepts are root metaphors, which are very different in orientation. Organizational culture is taken to refer to the underlying patterns of interpretations of formal practices, such as pay levels, hierarchy, and job descriptions, and informal practices such as norms, espoused values, rituals, organizational stories, jargon, humor, and physical environment. Conversely, researchers generally agree that climate is a measure of the surface manifestations of culture and is not entirely distinct from culture. Most argue that culture, due to its deep and often hidden embeddedness in organizations, can only be measured by qualitative methodologies, whereas climate as a more superficial characteristic of organizations can be assessed using quantitative questionnaire measures. Furthermore, whereas culture researchers are concerned with the manifestation of underlying assumptions which create shared values, climate researchers are more interested in the ways in which organizational members attend to these shared values (Kuenzi and Schminke, 2009). However, others would argue that these distinctions are largely artificial and it is true that both concepts of climate and culture are the subject of

continuing debate because of their lack of theoretical and conceptual underpinnings.

In defining the construct of organizational climate, it is also important to distinguish between global climate and facet-specific climate. Indeed, over the years, there has been much uncertainty and debate about whether climate should be conceived of as a multidimensional concept or a unitary concept. Initially, climate researchers focused on establishing a global conceptualization of organizational climate which could account for the total influence of situational variables in organizations, and how these impact individual attitudes and behavior. For example, Campbell et al. (1970) argued for a small number of common dimensions that constitute climate, including individual autonomy at work, the degree of structure imposed upon people's work roles, reward orientation (positive or negative), and warmth and support. Similarly, Jones and James (1979) proposed four dimensions of climate perceptions: job challenge and autonomy; role stress and lack of harmony; leadership facilitation and support; and work-group cooperation, friendliness, and warmth. However, the focus on climate as a global phenomenon has been riddled with conceptual and methodological problems. First, given the abundance of global climate definitions in the literature, researchers have been unable to reach a consensus on a single definition, leading to conceptual imprecision and ambiguity surrounding measurement. Existing research focused on global climate has also been criticized for lacking rigorous theoretical rationale.

These conceptual and methodological challenges have fueled a growing interest in facet-specific organizational climates over the past decade. For example, Clarke (2006) looked at a climate for *safety*, Anderson and West (1998) at a climate for *innovation*, and Martin and Cullen (2006) at a climate for *ethics*. Indeed, Schneider and Reichers (1983) initially suggested that work settings actually have many climates and argued for the study of facet-specific climates rather than global organizational climate. To this way of thinking, the choice of climate dimensions should be closely linked to the criteria of interests or climates 'for something.' This should reflect the specific strategic outcomes of the organization at hand, for example, a climate for justice, ethics, diversity, innovation, customer service, or safety. Because these each represent distinct aspects of an organizational environment, facet-specific climates can be seen as independent and may therefore be present simultaneously at any given time in an organization.

Although facet-specific climate research has helped to develop our understanding about how work climates impact individual and organizational performances, this approach has also led to substantial fragmentation in the field, with research on particular facets becoming splintered and published under different topical areas. Some suggest that this has led to poor integration and unification of the most recent research on organizational climate (Kuenzi and Schminke, 2009). Others also continue to argue that organizational climate is most usefully applied as a multidimensional construct and that some dimensions are generic and applicable to most organizations. Of course, there will be some which are unique or at least applicable to only a small range of organizations (e.g., climates for secrecy in the defense industry or for caring in health care organizations). One orientation to the mapping of climate that has proved powerful is the competing values model of organizations (Quinn and Rohrbaugh, 1981), which distinguishes among human relations, rational goal, open systems, and internal process constellations of organizational values.

The Competing Values Model

The competing values approach incorporates a range of fundamental dimensions of values into a single model. It calls attention to how opposing values exist in organizations and how organizations have different mixtures of values that influence their goals and how they go about achieving those goals. These values will most fundamentally manifest themselves in whether the organizational orientation varies more toward flexibility or control, and whether the focus of the organization varies more toward the external or internal environment. A major theoretical strength of this model is its derivation from four orientations to the study of organizational effectiveness reflecting long traditions in work and organizational psychology. Thus the rational goal approach (external focus, but with tight control within the organization) reflects a rational economic model of organizational functioning, in which the emphasis is upon productivity and goal achievement. The open systems model (external focus and flexible relationships with the environment) emphasizes the interaction and adaptation of the organization in its environment, with managers seeking resources and innovating in response to environmental (or market) demands. The internal process approach reflects a Tayloristic concern with formalization and internal control of the system in order that resources are efficiently used. Finally, the human relations approach reflects the tradition derived from socio-technical theory, emphasizing the well-being, growth, and commitment of the community of workers within the organization. By combining these orientations into one model, Quinn and Rohrbaugh aimed to provide a broad conceptual map of the domains of organizational theory over the twentieth century. Such a map is useful in identifying the required topography of a climate measure applicable to a wide range of organizations. The model is also useful in reflecting the means for implementing those values in terms of managerial practices and the ends or outcomes which are emphasized or which compete in each domain. The model does not propose that organizations will locate predominantly in one quadrant, but, reflecting the rich mix of competing views and perspectives in organizations, proposes that organizations will be active and give emphasis to each domain but with differing strengths.

Measuring Organizational Climate

Having established what we mean by 'organizational climate,' in this section, we shall explore the different statistical functions of organizational climate scores. Indeed, research on organizational climate continues to be hampered by a particular methodological debate. It concerns the practice of

aggregating individual employees' scores on climate dimensions and taking the mean as a representation of organizational climate. This has been referred to as a composition theory for climate (James et al., 2008) which proposes that the aggregation of individual climate perceptions (i.e., psychological climate) provides a powerful measure of organizational climate. Given that organizational climate is a collective phenomenon representing shared psychological meanings, statistical aggregation to this higher level construct requires perceptual agreement between individual climate scores. Therefore, the validity of aggregate climate used to describe organizations depends upon the demonstration of agreement between individual members and their perceptions. In such circumstances, the use of aggregated individual data to measure organizational climate is appropriate.

Nevertheless, the main methodological problem with this approach, a demonstration of shared conceptions for aggregate climates, has provoked much debate in the research literature. Indeed, writers have not specified what is an appropriate level of agreement. Some suggest that dichotomous questionnaire items should be used to measure climate and that the only items to be treated as descriptive of organizational climate should be those in which the frequency of endorsement is not significantly different from 0 to 100%. Others have suggested that 66% was reasonable, but few researchers have followed either prescription. The validity of aggregating climate perceptions to the organizational level is further called into question by the demonstration that there are significant differences between members of different organizational subgroups in their perceptions of climate. Such differences have been found between groups within the same organization, based on factors such as hierarchical level, departments, divisions, regions, and work groups.

One approach to overcoming the aggregation issue is to examine the level of inter-rater agreement between individuals within an organization, in relation to their perceptions of climate. A common way of achieving this is through the use of intraclass correlation coefficients. Such coefficients are based on a one-way analysis of variance and assesses the ratio of variation within organizations to variation among organizations. However, this coefficient has been criticized as inadequate which led to the development of the $R_{wg(j)}$ index of multiple item scales developed by James et al. (1993). This is a technique for assessing agreement among the judgments made on multiple item scales. Another salient approach is the average deviation (AD) index (Burke et al., 1999). Although there is continuing debate about the advantages and disadvantages of such orientations, these measures for justifying aggregation continue to be widely used. Indeed, it remains likely that organizational climate measures will continue to be used, despite there being no simple or widely agreed criteria for aggregation. Part of the problem is that the level of agreement within organizations will depend partly on the measures employed, the context, and the domains tapped by the measures. However, simply using the mean may mask profound differences between organizations and the variation of responses given by employees. Indeed, research within organizations has shown clear differences between hierarchical levels and departments in ratings of climate, suggesting a number of subclimates within each organization. Overall, when the level of analysis changes from the individual to the organization, the validity of the data is uncertain.

More recently, researchers have begun to explore new relationships between organizational climate and its antecedents and outcomes by using alterative statistical functions of climate scores. For example, Schneider et al. (2002) proposed the related construct of '*climate strength*' which captures within-group variability of perceptions of organizational climate. The researchers found that climate strength moderated the relationship between managerial practices (one of four dimensions of climate) and customer experience. In another study of 197 work units, Gonzalez-Romá et al. (2002) also examined the moderating influence of three climate strength facets (support, goals orientation, and innovation).

Alternatively, in a study of emergency planning committees, Lindell and Brandt (2000) used the constructs of '*climate quality*' (mean climate perceptions) and '*climate consensus*' (level of perceptual agreement on climate) as mediating variables in their analysis. Their results showed that in comparison to climate consensus, climate quality was more strongly related to both antecedent and outcomes variables. More recent research is therefore moving beyond the composition theory for climate, exploring the influence of more sophisticated statistical functions of climate scores.

Research on Antecedents and Outcomes

So what has research told us to date about the importance of organizational climate in predicting individual, group, and organizational outcomes? What factors influence the development of organizational climate in organizations? In this section, we shall begin by summarizing research evidence on the consequences of organizational climate for organizations and their members, before considering several important antecedents.

One of the earliest uses of the concept of climate was in research conducted by Lewin et al. (1939), who examined the effect of the leadership style of boys upon their work groups. Leadership style was categorized as autocratic, democratic, or laissez-faire and the work-group climates were described, respectively, as hostile, unproductive, and unenjoyable; busy, cooperative, productive, and enjoyable; and anarchic, unproductive, not cohesive, and unsatisfying. More recent research has concentrated on climate at work group, department, or organizational levels. As had been discussed, these supra-individual climates have been operationally constructed by aggregating individual perceptions of psychological climate to the appropriate level and using the mean to represent the climate at that level of aggregation. These organizational climate measures are now widely used in public and private sector organizations to determine the prevailing climate, often being called employee attitude surveys or employee opinion surveys.

One of the reasons why organizational climate surveys have become so widely used is that climate has been shown to predict organizational productivity and profitability, customer attitudes, innovation, team performance, OCBs, safety, and job

attitudes. For example, Patterson et al. (1997) found that an organizational climate oriented toward good human relations predicted 29% of the variation between companies in productivity and profitability in the UK manufacturing sector. In a study of 137 clusters of bank branches, Gelade and Ivery (2003) also found that global organizational climate was positively related with sales against targets, clerical accuracy, customer satisfaction, staff retention, and overall performance. Furthermore, Glisson and James (2002) found that positive climates predicted more favorable work attitudes in a study of 238 managers. This study also found evidence that organizational climate is distinct from culture. Overall, because of these strong associations between climate and performance, both researchers and practitioners remain intensely interested in the construct (Kuenzi and Schminke, 2009).

There has also been an increasing amount of empirical attention paid to facet-specific climates over the past decade. For example, Hofmann et al. (2003) explored the moderating effect of safety climate on the association between leadership (specifically leader–member exchange (LMX) and safety citizenship roles. Using multilevel analysis, group-level safety climate was found to moderate the LMX–safety citizenship roles relationship. In another facet-specific study, King et al. (2007) analyzed data from over 22 000 members of 131 health care organizations in the United Kingdom and found that climate for innovation was positively related to organizational performance and also moderated the relationship between work demands and organizational performance. Furthermore, Chen et al. (2007) adopted a group-level approach to explore the effects of team empowerment climate on an individual's sense of empowerment, whereas Maynard et al. (2007) collected data from 637 customer service engineers to examine how resistance to empowerment climate was related to team performance and customer satisfaction. These are just a few of many published studies which have examined outcomes of facet-specific climates over recent years.

But where do climates come from? What influences their emergence and development? Researchers have now started to pay more attention to the individual-, group-, and organization-level predictors of climate, mainly through quantitative cross-sectional field studies. However, relative to the amount of research examining the consequences of global and facet-specific climates, far fewer studies have so far examined climate antecedents. One antecedent that has received the most interest is that of leadership. For example, transformational leadership was shown to be a significant antecedent of climate for involvement in a study by Richardson and Vandenberg (2005). Similarly, in a study of over 2000 military soldiers, Zohar and Luria (2004) found transformational leadership to positively predict safety climate. In another leadership study, Ehrhart (2004) found that servant leadership was positively related to procedural justice climate, which itself was a mediator between servant leadership and OCB. Leader personality characteristics have also been explored as antecedents of facet-specific climate. In a study of 3445 employees in 383 US department stores, Mayer et al. (2007) found that leader agreeableness and conscientiousness were positively related to procedural justice climate, whereas neuroticism was negatively related, and extraversion unrelated. Finally, in a study of 212 bank employees, Walumbwa et al. (2008) found that contingent reward transactional leadership positively predicted procedural justice climate and procedural justice climate strength, which in turn, were related to satisfaction with supervisor, OCB, and organizational commitment. Research to date therefore suggests that leadership is a key mechanism through which organizational climate can be developed and nurtured to have a positive impact on outcomes.

However, an increasing amount of research has also looked beyond leadership to consider other important antecedents of facet-specific climates. In keeping with the theme of procedural justice, Tangirala and Ramanujam (2008) found that employee silence was a negative antecedent of procedural justice climate, which itself moderated the relationship between employee silence and work group identification, as well as professional commitment. Naumann and Bennett (2000) examined whether demographic similarity, group cohesion, and supervisor viability were antecedents of climate strength in a study of 323 bank employees. They found that procedural justice climate was indeed related to cohesion and supervisor viability, but not to demographic similarity, suggesting that shared climates can emerge even in highly diverse organizations. Finally, Pirola-Merlo et al. (2002) conducted research with 53 research and development teams and found that obstacles had a negative impact on team climate, which in turn, was positively related to team performance. Furthermore, team climate mediated the relationship between leadership and team performance. This is by no means an exhaustive list of research on climate antecedents, but serves to demonstrate the growing level of interest and diversity in the type of research currently being conducted in the field. We anticipate that this will only continue to grow as organizations are required to do more and more with less and less, and therefore require further understanding about how exactly contextual factors impact and shape the working lives of organizational members.

Conclusion

Theory and research on the phenomenon of organizational climate is continuing to develop and gain momentum in the organizational sciences. In a recent qualitative review, Kuenzi and Schminke (2009) identified 241 published empirical studies in the area. Indeed, because organizational climate is a phenomenon that researchers experience in practice, in working in different organizations, and because the measures of organizational climate relate to important outcome measures, it is likely that the concept will continue to be used. Progress has been made on how to best capture and operationalize the climate construct. However, the increasing focus on facet-specific climates means that the literature has become splintered and somewhat fuzzy in recent years. Future research endeavor must therefore be designed and conducted through a more unified theoretical and methodological lens to enable organizational climate scholars to better synthesize their research findings and move the field forward in a coherent and coalesced way.

Abstract

Organizational climate research represents one of the primary approaches to understanding work environment in organizations. Employee perceptions of organizational climate affect nearly all aspects of organizational life including employee attitudes and behavior, group processes, and organizational performance. Research on organizational climate gained momentum in the late 1960s and early 1970s, but waned in the 1980s as a number of conceptual and methodological challenges were raised by critics. The resolution of these challenges formed the foundation for contemporary research on climate, which has thrived over the past decade due to its usefulness in understanding workers' experiences and predicting organizational effectiveness.

Researchers and practitioners alike have been increasingly interested in the impact of the organizational context on important outcomes such as employee attitudes, group processes, and firm performance. One of the primary and most fruitful lines of research on these contextual factors has focused on the topic of organizational climate. Organizational climate is defined as "the shared meaning organizational members attach to the events, policies, practices, and procedures they experience and the behaviors they see being rewarded, supported, and expected" (Ehrhart et al., 2014: p. 2). The study of organizational climates is important in that they impact nearly all aspects of organizational life. To provide an overview of this important topic, below is summary of the history of organizational climate, its overlap with and distinctions from organizational culture, and how it has been conceptualized, measured, and studied.

History of Organizational Climate

The history of the organizational climate construct can be traced to research done by Lewin et al. (1939) on the effects of leadership on the 'social climate' that formed in groups of 10-year-old boys. They examined how democratic, autocratic, and laissez-faire leadership influenced the nature of the interactions among the boys. The critical aspects of this research were its focus on the group environment or climate as a whole and the importance of that climate for the group's functioning and performance. Interest in the environment of organizations as experienced by its employees continued to grow in subsequent decades, particularly the study of climate. The interest in organizational climate was aligned with the broader movement among organizational researchers to move beyond the focus on individual differences that had been the typical focus of industrial psychology. Thus, as the fields of organizational psychology (later merged with industrial psychology as industrial/organizational psychology) and organizational behavior began to grow through the 1960s, the concept of organizational climate attracted increasing attention by researchers.

By the late 1960s and early 1970s, research on organizational climate had proliferated, but that growth was quickly followed by a number of critical reviews of the literature. The concerns were many, including definitional issues such as whether climate was an attribute of individuals or organizations, the overlap of climate with other variables including job satisfaction and structure, the mixed findings between climate and performance, and methodological issues such as whether there was adequate consensus in climate perceptions to justify aggregation (Ehrhart et al., 2014). The resolution of these issues formed the foundation for contemporary research on organizational climate to be described in what follows. Before doing so, we first address another relevant issue surrounding the definition of climate: the relationship between organizational climate and organizational culture.

Organizational Climate versus Organizational Culture

The history of organizational climate is intertwined with the related concept of organizational culture. Although organizational climate and organizational culture have similarities, they are distinct constructs. Organizational culture has been defined as "a pattern of shared basic assumptions learned by [an organization] as it solved its problems of external adaptation and internal integration, which has worked well enough to be considered valid and, therefore, to be taught to new members as the correct way to perceive, think, and feel in relation to those problems" (Schein, 2010: p. 18). In early climate research in the 1950s and 1960s, the terms climate and culture were often used interchangeably as the domains of either had not been clearly articulated. A distinct literature on organizational culture emerged in the 1980s, and for many years the two concepts coexisted with little discussion of their relationships or overlap. More recently, however, this issue has received growing attention, including by Denison (1996), Ehrhart et al. (2014), Ostroff et al. (2012), Schneider et al. (2011b), and Zohar and Hofmann (2012).

There are many similarities between the concepts of organizational climate and organizational culture. Ehrhart et al.

(2014) identified several, including their common focus on the macro environment of the organization, their emphasis on the shared experiences of workers, the centrality of meaning that employees' experiences hold for them, the important role of leaders in influencing the climate or culture, and the constructs' influence on organizational effectiveness. Nevertheless, they and others (particularly Denison, 1996) have also identified several critical differences between climate and culture. One is the theoretical tradition of each variable, as organizational climate was primarily developed within the field of psychology and organizational culture was drawn from the field of anthropology. An implication of this difference has been that climate has been more typically studied using quantitative methods whereas culture research has more traditionally used qualitative methods (although there has been growing use of organizational culture surveys over the years, which has served to confound the confusion between the constructs). Climate and culture also differ with regard to their breadth, as culture typically includes a much broader range of variables (such as language, stories, rituals, traditions, behavioral norms, dress, and physical arrangements) and climate is more focused on how employees perceive the organization's policies, practices, and procedures. Similarly, organizational culture includes deep assumptions that may not even be in the conscious awareness of employees; climate clearly exists within the conscious awareness of employees. Because of organizational culture's breadth and depth, it is notably difficult to change. Organizational climate is not easy to change either, but is likely more susceptible to organizational change interventions. Finally, research on organizational climate has developed such that it has a strategic focus. In other words (and as we describe in more detail in later sections), there are many climates within organizations which relate to the strategic outcomes or processes in organizations such as justice, safety, or service (Schneider, 1975). Because culture tends to include the totality of employees' experiences in their organizations, it is more commonly studied as a general concept without a focus.

The complexities surrounding the constructs of organizational climate and organizational culture raise questions about how the two constructs are related to each other. Schneider et al. (2011b) emphasized culture as both forming a foundation for strategic climates (which then predict strategic outcomes) and making the organization an attractive place to work (which results in a strong organizational reputation and high employee retention). Ostroff et al. (2012) similarly placed culture as a foundation for climate, noting that climate focuses on what happens in the organization as perceived by employees, and culture explains why those things happen. Furthermore, they describe the policies, practices, and procedures in the organization as the linking mechanism between culture and climate, such that those practices are a manifestation of cultural assumptions and subsequently become the focus of employees' climate perceptions. Zohar and Hofmann (2012) emphasized organizational climate as an overall gestalt perception based on the pattern of cultural artifacts employees experience in the organization. These perceptions inform understandings of the enacted values in the organization, which when contrasted with the espoused values, provide insight into the deeper layers of culture (i.e., the organization's core values and assumptions). Although each of these perspectives has its own emphasis, they share in common the idea that both organizational climate and organizational culture offer unique insights into organizational functioning and approaches integrating both concepts offer much potential.

Molar Climate versus Focused Climate

As mentioned previously, there were a number of concerns voiced in the 1970s as the climate construct grew in prominence, and two of the criticisms of climate were its overlap with other constructs and its inconsistent relationship with outcomes. Some early efforts to develop measures of climate attempted to capture the full breadth of work environment attributes as experienced by workers, or what has been referred to as the molar climate approach. The problem is that such measures captured many other organizational constructs with their own independent literature, like structure, leadership, stress, and cooperation. In addition, attempts to show that molar climate measures related to effectiveness were inconsistent because the measures lacked focus or a direct link to the criteria of interest. Schneider (1975) argued that to address these problems, climate should be studied with a particular focus or a climate for 'something.' Thus, instead of trying to measure the totality of the work environment, he asserted that the goal should be to measure those aspects of the environment that are most relevant for predicting a specific criterion. In the years following, there was a divergence in the field between research on molar climate and focused climate.

Across research on molar climate, a variety of dimensions within various taxonomies have been proposed. One such taxonomy that sought to organize the molar climate literature up to that point was proposed by Ostroff (1993). She organized climate dimensions into three general categories: affective, cognitive, and instrumental. The affective climate category addresses relationships among employees and includes the dimensions participation, cooperation, warmth, and social rewards. The cognitive category captures how individuals relate to their work, and includes the dimensions of growth, innovation, autonomy, and intrinsic rewards. Finally, the instrumental category includes climate dimensions related to how tasks are performed, such as achievement, hierarchy, structure, and extrinsic rewards. Another approach by Patterson et al. (2005) was developed by linking climate dimensions to the competing values framework (CVF). The CVF results from crossing the dimensions of flexibility versus control and internal versus external orientation, resulting in four approaches to organizational effectiveness: the human relations approach, the internal process approach, the open systems approach, and the rational goal approach (Quinn and Rohrbaugh, 1983). In the development of their Organizational Climate Measure (OCM), Patterson et al. (2005) organized 17 climate dimensions within each of these approaches, such that the human relations model included the dimensions of autonomy, integration, involvement, supervisory support, training, and welfare; the internal process model included the dimensions of formalization and tradition; the open systems model included the dimensions of innovation and flexibility, outward focus, and reflexivity; and the rational goal model

included the dimensions of clarity of organizational goals, efficiency, effort, performance feedback, pressure to produce, and quality. Because of the strong correlations across a number of molar climate dimensions, some have proposed that molar climate approaches capture the extent to which an organization is a positive place to work, or a general climate for well-being (Schneider et al., 2011a).

Although molar climate research has continued to this day, the dominant approach to studying organizational climate has been the focused climate approach. The earliest efforts to study focused climates were on the climate for customer service and climate for safety, and both of those research streams have produced a large body of research. Beyond service and safety, the focused climate approach has been applied to a number of additional areas. A partial listing of these climates would include climate for innovation, justice climate, ethical climate, diversity climate, leadership climate, climate for sexual harassment, and climate for initiative, among many, many others (Kuenzi and Schminke, 2009). The large number of applications of climate has resulted in some researchers proposing ways of categorizing these various focused climates. For instance, Schneider et al. (2011a) distinguished between two types of focused climate. Strategic climates focus on the achievement of the organization's strategic goals that can typically be measured by external criteria, such as service, safety, or innovation. In contrast, process climates focus on the organization's internal processes, and include justice climate or ethical climate. Another organizing scheme for focused climates was proposed by Kuenzi and Schminke (2009). They proposed four general categories of focused climates: climates focused on behavioral guidance (e.g., ethics and justice), climates focused on involvement (e.g., participation, support, and empowerment), climates focused on development (e.g., learning and creativity), and climates focused on core operations (e.g., service and safety).

In a similar way that organizational culture can serve as a foundation for climate, some have proposed that molar climate and process climates may best be conceptualized as serving as a foundation for strategic climates (Ehrhart et al., 2014). Because strategic climates involve those aspects of the work environment that are most relevant for the accomplishment of the relevant strategic goals, they are the more proximal predictor of outcomes. Nevertheless, workers are unlikely to be motivated to pursue the organization's strategic goals unless they are treated well and have the necessary resources and training to be successful. In subsequent sections describing different approaches to studying climate, we will highlight research that supports this conceptualization and that also provides examples of various approaches to studying organizational climate.

Measuring Organizational Climate

In addition to the early concerns voiced by critics over the conceptualization of climate, there were also concerns about its measurement. One of the core problems was confusion over the proper level of analysis for the construct. Although historically the writing and research on climate had emphasized its role as a macro construct functioning at the organizational level, it was typically measured based on individuals' reports. With most of the interest in climate coming from psychological researchers, the tendency early on was to subsequently study it at the individual level rather than aggregating to a higher level, raising questions about the proper level of analysis for the construct. One important resolution of this issue came from James and Jones (1974), who distinguished between climate studied at the unit level (which was labeled as organizational climate) and at the individual level (which was labeled as psychological climate). Although research on both psychological climate and organizational climate continues to this day, recent literature has focused more on organizational climate most likely because of the historical emphasis of climate as a macro construct and the usefulness of organizational climate for understanding important unit-level outcomes. For a recent review of the literature on psychological climate, see James et al. (2008).

Related to the level of analysis issue was another criticism that climate seemed to overlap with job attitudes, particularly job satisfaction. The shift to the unit level of analysis addressed this concern in part, but another aspect of it had to do with the content of climate items. Because some climate measures emphasized individuals' affective responses to their work responses, the unique contribution of climate beyond work attitudes was questioned. The resolution of this concern, as advocated for by Schneider (1975) and Glick (1985), was for climate measures to focus on description rather than evaluation and to use a unit referent for climate items. In other words, if employees are asked to describe the shared experiences of all employees in the workplace, then the overlap with job attitudes like satisfaction is minimized. Furthermore, the unit referent reinforces that climate is a property of organizations or their units, not individuals. Recent research suggests that using a unit referent also increases the validity of the climate construct for predicting performance outcomes (Klein et al., 2001; Wallace et al., in press; Whitman et al., 2012).

Once researchers have decided their focus is on organizational climate as a unit-level construct measured by descriptive items with a unit referent, they still must demonstrate justification for aggregating individual reports to a higher level of analysis. The amount of agreement that is needed, how to statistically test for that agreement, and the number of employees needed from the unit to test for agreement has been the subject of much discussion for several decades, going beyond organizational climate research to include any unit-level constructs that researchers wish to study based on individual-level reports. Although many alternatives exist, the most common within-group agreement statistics found in research in industrial/organizational psychology and management is $r_{WG(j)}$ (James, 1982; James et al., 1984). Within-group agreement statistics are often coupled with intraclass correlations, such as ICC(1) and ICC(2), that combine information on agreement and reliability. More in-depth information on handling these statistical issues can be found in Bliese (2000) and LeBreton and Senter (2008). The take-home message is that researchers should demonstrate that individual-level climate data can be meaningfully aggregated to represent the climate of the unit as a whole.

One final point of clarification on the topic of measurement is that the climate literature suggests that it can operate at

multiple levels of analysis. Thus, there may be an overall climate in an organization as a whole, but there also may be subclimates in departments, stores, or work groups. In some cases the climate at one level may be dominant and studying climate at other levels may not be appropriate. More likely is the case that climate operates at multiple levels simultaneously and that different climate issues are more relevant depending on what level is the focus of the research. An excellent example of such multilevel climate research is Zohar and Luria's (2005) research on safety climate. Among other findings, they demonstrated that the safety climate in a manufacturing plant predicts the safety climate of the work groups in that plant, which subsequently predicts the group's safety behavior.

Research on Organizational Climate

The early popularity of organizational climate waned with the concerns raised by many critics and the growing interest in organizational culture. Nevertheless, since the late 1990s interest in organizational climate has risen dramatically (Kuenzi and Schminke, 2009), and research on the topic has expanded and in numerous directions. Much of the early interest in organizational climate was based on its hypothesized importance for organizational effectiveness; therefore, it is not surprising that one of the major lines of research on the topic has been in demonstrating its relationship with critical organizational outcomes. Although molar climate has been demonstrated to relate to organizational performance (e.g., Patterson et al., 2004), the relationships have generally not been as strong as those found for focused climates as demonstrated by several meta-analyses in recent years. For instance, Hong et al. (2013) showed that service climate was significantly related to service performance and customer satisfaction, in addition to financial performance. In the safety domain, meta-analyses by Christian et al. (2009) and Beus et al. (2010) have demonstrated significant results across studies for a relationship between safety climate and safety outcomes like accidents and injuries. As a final example, Whitman et al. (2012) showed that justice climate was significantly related to unit performance.

In light of the strong evidence for focused climate's relationships with organizational effectiveness, researchers have begun to incorporate more complexity in their research to better understand climate's effects. One issue addressed by this research is how climate has its effects on outcomes (i.e., what are the mediators of this relationship?). For instance, researchers have investigated that service climate's relationship with customer outcomes is mediated through employee behaviors toward customers (Schneider et al., 2005). Research from the safety domain has suggested that motivation also plays a role in the process, such that the climate increases employee motivation, which then is related to their behavior and the subsequent outcomes (Neal and Griffin, 2006). Such research has been helpful in detailing the processes through which organizational climate influences outcomes.

Mediation models have not been limited to studying the mediators of climate's relationship with outcomes. Climate itself has been studied as a mediator, explaining how other influences on the organization and work units influence employees and unit outcomes. From the beginning (e.g., Lewin et al., 1939), climate has served as an explanatory variable to understand how leaders have their influence. In other words, as leaders create policies, procedures, and reward systems in their units, employees experience those systems and form shared gestalt perceptions of what the priorities are in the unit (i.e., climate), which subsequently guides employee behavior and ultimately the unit's outcomes. In the same way that climate research has distinguished between molar and focused approaches, research on leadership's relationship with climate has begun to distinguish between general and focused leadership. Meta-analytic results from Hong et al. (2013) on service climate demonstrated that both general leadership and service leadership had significant relationships with service climate, but the strength of the relationship was stronger for the focused (i.e., service) leadership approach. Ehrhart et al. (2014) explain these findings in terms of the effects of leadership on employee motivation. When leadership is generally positive, employees respond favorably and are more motivated, but also need more information on where to target their motivation, and that is what the focused leadership communicates. In addition to leadership, other variables have been studied as potentially foundations for the development of focused climates. Examples include work facilitation (Schneider et al., 1998) and organizational resources (Salanova et al., 2005) as foundations for service climate, and organizational rewards as a foundation for safety climate (Wallace et al., 2006). This research is in line with the idea that a molar climate for employee well-being (and possibly related process climates) is needed in order for more focused climates to be effective.

In addition to climate studies focusing on mediation, researchers have also studied moderated relationship involving climate. Perhaps most common is to study moderators of climate's relationship with outcomes. The assumption of this research is that climate will have stronger effects in some situations or contexts than in others, so the research is focused on identifying the critical variables that influence this variation. The relevant moderators often will be specific to the focused climate. For instance, service climate has been shown to have stronger effects when levels of customer contact are higher and the product is less tangible (Dietz et al., 2004; Mayer et al., 2009a), and safety climate has been shown to have stronger effects on injuries and errors when complexity was higher (Hofmann and Mark, 2006). There are some moderators, however, that can affect all climates. For instance, the moderator that has perhaps received the most attention in the organizational climate literature is climate strength. As opposed to traditional climate research that focuses on the level of the climate in the unit (typically the unit's mean climate score), the climate strength approach focuses on the variability within the unit in climate perceptions (e.g., the standard deviation). Researchers studying climate strength as a moderator of the relationships between climate level and outcomes typically hypothesize that the strength of those relationships will be stronger when the climate is stronger, such that a positive climate will have a more positive impact when unit members agree it is positive and a negative climate will have a more negative impact when unit members agree it is negative. This approach has been applied to research on service climate (e.g., Schneider et al., 2002), justice climate (e.g., Colquitt et al., 2002), and molar climate

(e.g., Lindell and Brandt, 2000), among many others. The research findings on this hypothesis have been somewhat mixed perhaps as a result of the lack of sufficient variability in climate strength to reveal significant moderated relationships (Ehrhart et al., 2014). Nevertheless, the climate strength approach has continued to grow, and researchers have begun to examine what causes climates to be strong or weak, as well as possible direct outcomes of climate strength.

A final general direction of climate research has been to study climate as a moderator of other individual- or unit-level relationships. One theme in early climate research was that certain personal characteristics of workers would matter more or less depending on the climate. More specifically, if the characteristics were aligned with the climate, then positive outcomes (e.g., performance) would result, and if they were not aligned, then negative outcomes (e.g., stress) would result. Other variations of this thinking were similar to the idea of situational strength (Mischel, 1968), such that certain climates were thought to encourage and others discourage the display of individual differences (Schneider, 1975). Recent research along these lines has demonstrated that employees' service orientation is a significant predictor of customer-oriented behaviors when service climate is high but not when it is low because a high service climate allows employees with high customer orientation the opportunity to display customer-oriented behaviors (Grizzle et al., 2009). Climate has also been studied as a moderator of unit-level relationships with outcomes, such that certain unit-level characteristics or processes are less likely to be successful unless the context (i.e., the climate) is right. Examples can be found in research on innovation climate with regard to outcomes of process innovations (Baer and Frese, 2003) and in the domain of safety climate with regard to safety training (Burke et al., 2008).

Future Directions

Many of the concerns of early climate research have been addressed, but as climate researchers continue to become more sophisticated in their thinking, it will be important to revisit some of these concerns in new ways as well as to examine new issues that have surfaced as the field has advanced. One area to revisit is the relationship between climate and culture. Although the distinction between the two constructs has been made, we are left with how they can be integrated together. As described above, there has been increasing attention in recent years in the theoretical connections between the constructs, but little empirical research has resulted as of yet. It is likely that it will change in coming years, especially with regard to how organizational culture across levels (assumptions, espoused values, and artifacts; Schein, 2010) serves to support specific strategic climates in organizations.

Another area that is likely to see increased attention is the development of climate over time. There is some theoretical work hypothesizing how climates are formed, but little empirical work. Schneider and Reichers (1983) suggested that climates develop in three different ways. First, as individuals interact with each other, they will converge on shared meanings (symbolic interaction approach). Second, homogeneity can occur due to the way employees are attracted and selected to the organizations and eventually how individuals that do not fit well will leave through attrition. Finally, climates can develop as individuals are exposed to the same practices, policies, and procedures (i.e., a structuralist approach). More recently, Roberson and Colquitt (2005) integrated network theory with climate research to explain how justice climates can emerge and to identify some of the barriers to that emergence in teams. Nevertheless, neither of these theories addresses how much influence leaders have on climate development or if climates can change over time as feedback is received by the managers from organizational outcomes or employees. Again, little longitudinal research on climate has been conducted, so our understanding of how climates are created and how they change over time is mainly theoretical at this point.

A third area for future research is on climate across levels of analysis. As there has been an increased recognition that individuals and organizational units are interdependent, there has been a steady increase in multilevel research across many domains. Zohar and Luria (2005) provided an excellent demonstration of how both climate level and climate strength operate across manufacturing plants and the work groups within those plants. In other areas, there has been interest in how strategies and values 'trickle down' from top management to managers to employees (Mayer et al., 2009). More research is needed clarifying the issues that are most relevant for climate across levels and how climates at different levels can work synergistically or at cross-purposes.

Finally, in coming years we are likely to see more research on how multiple types of climate operate simultaneously. There are many climates that have been linked to similar outcomes such as performance and customer satisfaction. However, we do not know much as to how multiple climates can have a synergistic effect, neutralizing effect, or possibly even compete against each other to affect employee attitudes and organizational outcomes. Some very preliminary work has already been done in this area; for instance, McKay et al. (2011) studied both diversity climate and service climate and found that diversity climate had the strongest relationship with customer satisfaction when both service climate and minority representation levels were high. However, more theoretical and empirical work is needed in this area to shed light on such issues as how the relationship between process and strategic climates operates and the implications for units when there are competing priorities from multiple strategic climates.

Conclusion and Implications

Research on organizational climate is growing and expanding in numerous directions. Not only is it being studied in new and exciting ways, but it is being applied in an increasing number of domains. This growth is testament to the usefulness of the construct for understanding employee experiences in organizations and how they contribute to organizational effectiveness. In that sense, organizational climate is a very practical construct; indeed, Johns (2006) has suggested that it is impossible to understand behaviors in organizations without understanding the situation. Thus, we would be remiss if we did not briefly highlight the practical implications of research

on organizational climate to the functioning of organizations. Perhaps the most important lesson from the literature on organizational climate is that of alignment. If managers have strategic goals they wish to accomplish, then the climate literature suggests the importance of aligning their prioritization of those goals through the messages that are sent in the organization's policies, practices, procedures, and reward systems. If those strategies are simply espoused by management but not enacted through their behavior and the systems they create, then employees will be unlikely to be motivated to work toward achieving those goals. Climate surveys can assist managers in diagnosing these issues within their organization. For instance, climate surveys can help assess if there is alignment between the organization's strategic goals and its policies, practices, and procedures as perceived by employees. It is not uncommon for top-level managers to have different perceptions of organizational climates than their employees, so if employee perceptions are not assessed, managers may not have an accurate picture of what is happening in their organization. By examining specific dimensions and items in climate surveys, managers in organizations can derive specific actionable steps to help make the desired climates become more salient to employees. In addition, surveys addressing molar or process climates can help leaders understand the foundation they must establish in order to build the strategic climate they desire. Thus, addressing organizational climate in all of its manifestations can provide an evidence-based framework for organizational change and, ultimately, organizational effectiveness.

Organizational Commitment

Howard J Klein and Heeman Park, The Ohio State University, Columbus, OH, USA

Abstract

Organizational commitment is the psychological bond an employee has to their employing organization. Commitment has been one of the most frequently examined constructs in organizational research because of the demonstrated impact it has on outcomes important to individuals and organizations. In this article, we define commitment, discuss the evolution of the construct, overview the outcomes and antecedents of commitment, contrast commitment to other related constructs, and outline current issues in the study of commitment requiring attention in future research.

Commitment is a psychological bond that an individual forms with a particular foci or target. Our focus is on organizational commitment and we will henceforth use the term commitment to refer to the commitment an employee has to their employing organization, even though bonds can be formed between employees and other organizations (e.g., client organizations, professional associations, unions) as well as to numerous other workplace targets (e.g., team, supervisor, goal; Becker, 1992; Reichers, 1985). Commitment is a frequently examined construct, because of the demonstrated impact it has on outcomes important to individuals and organizations such as absenteeism, turnover, motivation, performance, prosocial behaviors, and well-being (Becker et al., 2009; Mathieu and Zajac, 1990; Meyer et al., 2002).

Commitment has been studied for decades and many definitions and conceptualizations of commitment have emerged over time. Commitment has often been referred to as a work attitude, but the nature of the construct does not fit current definitions of an attitude. Instead, commitment is more accurately conceptualized as a psychological state (Meyer and Allen, 1991). Klein et al. (2012) proposed a definition that we adopt here that is applicable to any target, excludes confounds present in prior definitions, and highlights the distinctiveness of commitment bonds. In the past, the term commitment has been used to encompass a wide range of different types of bonds or attachments (e.g., Kanter, 1968). Klein et al. (2012) define commitment as a particular type of bond and differentiate it from other bond types (e.g., instrumental or identification). They specifically define commitment as "*a volitional psychological bond reflecting dedication to and responsibility for a particular target*" (p. 137). Klein et al. (2012) also present the process model of commitment shown in **Figure 1**. We overview the outcomes and antecedents of commitment identified in this model after briefly summarizing prior treatments of the construct.

Evolution of the Construct

The earliest research on commitment was conducted by sociologists who examined group attachments as a mechanism for generating and sustaining social order (e.g., Parsons, 1951) or in understanding social roles (e.g., Gouldner, 1960). Scholars in psychology and management began to pay more attention to commitment in the 1960s, with that early commitment research taking two very different perspectives, reflecting either a behavioral or psychological view. The behavioral view considered commitment to be the result of behavior, with prior acts 'committing' people to a future course of action due to a desire for consistency, sense of obligation, and the 'sunk costs' of previously invested time and effort (e.g., Becker, 1960; Kiesler, 1971; Salancik, 1977). Work from the behavioral perspective provided important insights into the phenomena of commitment, particularly in terms of decisions to stay with and contribute to organizations based on behavioral consistency, investment, and exchange. This focus on behavior and exchange was, however, viewed by many as providing an incomplete explanation.

The alternative psychological or attitudinal view considered commitment as a driver of behavior rather than resulting from behavior. This perspective focused on how individuals identify or relate to their organization (e.g., Buchanan, 1974; Porter et al., 1974). From this perspective, commitment was presented as an important determinant of turnover and other outcomes, and as an alternative to job satisfaction that could be measured and influenced. Mowday et al. (1982) summarized the early work conducted from these perspectives and attempted to reconcile the two views, with primacy given to the psychological view.

Within and across these two views, there were numerous variations in focus and definition (see Klein et al., 2009), leading to efforts at developing integrative frameworks. For the past 20 years, the most popular of those frameworks has been the three-component model (TCM) presented by Meyer and Allen (1991). In this model, commitment is defined as "a force that binds an individual to a course of action of relevance to one or more targets" (Meyer and Herscovitch, 2001: p. 301), with that force experienced as one or more mind-sets – affective ('want to' or desire), normative ('ought to' or obligation), and continuance ('have to' or cost). This model, presented in **Figure 2**, has generated a tremendous amount of research regarding the antecedents and consequences of commitment. The TCM has, however, been criticized for a number of reasons including a lack of theoretical justification for the three mind-sets and being overly broad, with definitional overlaps with closely related constructs, leading to the Klein et al. (2012) reconceptualization.

Commitment Outcomes

As noted previously, Commitment is associated with a number of desirable consequences. The Klein et al. (2012) model, shown in **Figure 1**, proposes two immediate outcomes (i.e., continuation and motivation) with action and the results of those actions (e.g., performance) being more distal outcomes. Continuation includes both the intention to continue with the organization and continuation behaviors. In short, committed individuals are less likely to withdraw from the organization. Meta-analyses (Mathieu and Zajac, 1990; Meyer et al., 2002) have consistently demonstrated negative relationships between commitment and turnover intentions, actual turnover, and other withdrawal behaviors (e.g., tardiness, absenteeism).

In terms of motivation, high commitment results in individuals' allocating more effort and resources in support of the organization and being more willing to make trade-offs in favor of the organization when allocating constrained resources such as time and attention (Klein et al., 2012). The relationship between commitment and motivation has been supported in prior research, summarized in the above referenced meta-analyses. Higher performance, both inrole and extrarole (e.g., organizational citizenship behaviors), can be expected to result from higher commitment, but indirectly, through the effects of continuation and motivation (Klein et al., 2012). Prior research supports these relationships, with stronger effects generally observed for extrarole than inrole performances.

Antecedents of Commitment

A vast number of factors have been identified as antecedents of commitment. The process model shown in **Figure 1** suggests that four proximal states are the immediate determinants of commitment with an inclusive set of more distal antecedents, organized by level that can influence the development of commitment through the four proximal states (see Klein et al., 2012). The four proximal states, which based on cognitive and emotional evaluations of the target and environment, are salience, positive affect, trust, and perceived control. First, based on field theory, the more salient the organization, relative to other potential commitment targets, the more likely that commitment will develop. Stated differently, people are more likely to develop a commitment bond to when they feel closer to the organization.

The second factor is positive affect. Individuals are more likely to dedicate themselves to and care about positively evaluated organizations than negatively evaluated organizations. This is based on approach motivation (i.e., individuals approach pleasurable situations and avoid painful situations) among other theories and is supported by the positive relationship demonstrated between commitment and satisfaction. Trust, the acceptance of some vulnerability based on positive expectations that others will reciprocate, is the third proximal state. Without trust in the organization, the dedication that is at the core of commitment is unlikely. The final proximal state, perceived control, is based on the theory of planned behavior, social cognitive theory, and other research. Essentially, individuals are more willing to commit to an organization when they feel they have a sense of control over the situation and confidence in their ability to meet the demands of their work role.

A wide range of factors influence those proximal states, which are grouped, as illustrated in **Figure 1**, from individual characteristics to target, relational, organizational, and societal factors. Individual level factors are attributes of the employee such as values and personality traits. Personal values such as work ethic and work centrality have been shown to lead to organizational commitment, as has the congruence between personal and organizational values. Personality traits found to relate to commitment include locus of control, conscientiousness, extraversion, and regulatory focus. Other individual differences shown to influence perceptual evaluations, such as trait affect, also influence commitment via the above proximal states.

A second set of antecedent factors arises from the social relationships that individuals have, both work and nonwork. It has been shown, for example, that having a dense friendship network is positively associated with commitment (Morrison, 2002). In addition, both social influences and exchanges resulting from these relationships can impact the identified perceptual evaluations and subsequently commitment. Examples of these social influences include what others think and say about the organization and the commitment of others. Social exchanges include the effects of perceived organizational support, supervisor supportiveness, and leader–member exchange.

With the organization as the target, target and organizational characteristics become a single category. Target characteristics include factors such as the psychological proximity of the organization, which impacts salience. Similarly, characteristics such as the legitimacy and reputation of the organization can influence commitment through evaluations of trust and positive affect. Other organizational factors that would impact the more proximal states include culture (and subcultures) and climate relative to numerous foci (e.g., safety, justice productivity, burnout). Finally, an organization's human resource practices can facilitate commitment bonds between employees and the organization. For example, Wayne et al. (2013) found that family supportive organizational practices are positively related to an employees' organizational commitment via the family's positive affect toward the organization.

The final antecedent category reflects societal-level factors – the broader socioeconomic environment in which the individual and organization are embedded. Because national culture shapes perceptions and ascribed meaning, cultural factors can influence the proximal states that determine commitment. Uncertainty avoidance, power distance, and collectivism, for example, can impact perceptions of control and trust, and have been shown to influence commitment. Macroeconomic factors can similarly impact perceptions and, in turn, commitment. Factors relevant to target salience and trust toward an organization, for example, include a country or region's economic conditions, business system characteristics, and labor market features (e.g., segmentation, strength, and role of unions).

Related Constructs

The distinctions between commitment and several related constructs have often been unclear because of the various, frequently confounded, prior definitions and measures of commitment. Below we address the distinctions and relationships between commitment and satisfaction, identification, motivation, engagement, and burnout.

Satisfaction

Prior definitions of commitment have blurred the boundary between commitment and job satisfaction by emphasizing affective attachment. As a result, some authors have suggested

that satisfaction and commitment can be combined into an overall job attitudes composite (Harrison et al., 2006) or even that commitment is a redundant and unneeded construct given the empirical overlap (Le et al., 2010). Although meta-analytic investigations have shown the two constructs to be highly related, there are conceptual distinctions that can be made between satisfaction and commitment. For example, attitudes such as satisfaction involve evaluative judgments (i.e., one's summative evaluation of the organization), whereas commitment, as defined here, does not involve an affect-based evaluative aspect. The causal ordering of the relationship between satisfaction and commitment has also been of interest and a debated issue. Some scholars have asserted that satisfaction causes commitment (e.g., Mowday et al., 1982) and others the opposite (e.g., Bateman and Strasser, 1984). Conceptually, we conclude that a reciprocal causal relationship (e.g., Farkas and Tetrick, 1989) is the most appropriate view, with satisfaction being a stronger antecedent than consequence. Specifically, satisfaction likely impacts commitment through its primary antecedents. That is, job satisfaction should facilitate commitment, as individuals are more likely to commit to positively evaluated targets. In turn, being committed to an organization likely makes the positive aspects of the organization more salient, biasing subsequent affect. Additional empirical research is needed to tease apart and verify the casual ordering of these relationships, over time and within person, using more recent and less confounded measures.

Identification

Prior definitions of commitment have also blurred the boundary between commitment and identification. For example, Porter et al. (1974) in part defined commitment as the strength of an individual's identification with a particular organization. Identification is a type of bond, like commitment, but there are unique aspects of commitment not captured by identification and vice versa. For example, the 'forming of oneness' with the target or the notion that the target becomes part of the individual's self-concept or image is central to identification (Riketta, 2005). Others have further detailed the conceptual differences and the need to better differentiate these constructs (see Mael and Ashforth, 1992; Meyer et al., 2006). Meta-analyses (e.g., Riketta, 2005) have demonstrated very strong correlations between identification and commitment. This is partially due to prior confounds in definition and measurement, with some prior measures of commitment largely indistinguishable from measures of identification (Klein et al., 2014). Yet studies have demonstrated empirical distinctions (e.g., Mael and Ashforth, 1992; Riketta, 2005). Thus, both conceptual and empirical evidence supports the distinctiveness of the two constructs (Riketta, 2005) and the existing evidence suggests that social identities are more likely to be antecedents than a consequence of commitment (Meyer et al., 2006).

Motivation

Some authors have defined commitment as a force (e.g., Meyer and Herscovitch, 2001), and motivation is typically defined as a set of internal and external forces that initiate behavior and determine its form, direction, intensity, and duration (Pinder, 1998). Meyer et al. (2004) proposed a model that presents motivation and commitment as related yet distinguishable concepts, with commitment being one of several energizing forces that constitute motivation. Klein et al. (2012) position commitment as distinct from motivation, with motivation being a primary commitment outcome as described above. In addition, since commitment is one of several determinants of motivation, other factors (e.g., needs, incentives) may be more salient in determining motivation at a given point in time (Meyer et al., 2004). Klein et al. (2009) summarize additional arguments for the distinctiveness of these two constructs.

Engagement

A concept sometimes defined in motivational terms (e.g., Kahn, 1990; Rich et al., 2010) is engagement. Other authors define engagement as a trait, state, presence/enthusiasm, and the opposite of burnout (e.g., Macey and Schneider, 2008; Schaufeli et al., 2002). Because of this definitional diversity, it can be challenging to differentiate engagement from commitment. Across all these definitions, engagement would be expected to relate positively to commitment. When defined in motivation terms (i.e., the willingness to expend personal energies on behalf of a target, or the harnessing of oneself to a role), engagement is an expected, motivational outcome of commitment. Of these varied definitions, those that discuss engagement as a state are most similar to commitment; yet state engagement is frequently conceptualized as a broad, higher order concept incorporating commitment and other constructs. For instance, Macey and Schneider (2008) discuss state engagement as including energy, absorption, satisfaction, involvement, commitment, and empowerment. Similarly, Schaufeli et al. (2002) conceptualize engagement as being involved, dedicated, enthused, inspired, committed, engrossed, and attached to one's work. Note that in defining commitment in terms of dedication, Klein et al. (2012) were not equating commitment with the dedication dimension in the Schaufeli et al. typology.

Burnout, Stress, and Well-being

Given that engagement is sometimes defined as the opposite of burnout, and the above-noted positive relationships between commitment and engagement, it is not surprising that commitment has been found to relate negatively to burnout (e.g., Cropanzano et al., 2003). In addition to burnout, research has consistently demonstrated associations between commitment and other employee physical and psychological health outcomes. Specifically, positive outcomes have been demonstrated with employee well-being (including physical well-being and physical general health, and mental health) and negative associations with physical and mental health complaints (including anxiety and depression), burnout and stress (see Meyer and Maltin, 2010). In addition to these main effects, several other studies have examined the role of commitment in buffering or mitigating the negative effects of perceived stressors on tension, anxiety, burnout, and depression. Commitment is thought to provide a sense of purpose and resilience, serving as a resource to attenuate the harmful

effects of stressors. Results are generally supportive of this moderating effect, though there are some inconsistencies in the findings (Meyer and Maltin, 2010).

Despite this evidence that commitment is generally positively associated with well-being, there may be situations where commitment may threaten a person's sense of well-being and lead to negative outcomes, resulting in what Reilly (1994) termed the "paradox of commitment". First, commitment may actually increase stressor–strain relationships because highly committed employees are likely to experience greater stress stemming from the increased salience of job demands relative to less committed employees who may not care. Second, commitment may negatively impact well-being when there are competing commitments – commitments that are in direct conflict or simply in competition for an individual's limited time or attention (Mathieu and Zajac, 1990). Similarly, over commitment – when the strength of a commitment results in an individual expending levels of time and effort that are not sustainable – can also result in high levels of stress and burnout (Schaufeli et al., 2002). A final potentially negative consequence of commitment on well-being pertains to the cessation or loss of a commitment, which has not been adequately considered in prior research. In addition, much of this research has been cross sectional, and longitudinal studies are needed to better understand how commitment relates to these employee-relevant outcomes. The evidence to date, however, does suggest that commitment has important consequences for employees themselves.

Issues Needing Research and Resolution

Competing Conceptual Definitions

As reviewed by Klein et al. (2009), numerous conceptualizations of commitment can be found in the literature. Inherent in this definitional debate, which has implications for the relationship between commitment and other constructs, is the location of the construct boundary. For example, investments that create a bond (e.g., sunk costs, side bets; Becker, 1960) as well as goal or value congruence (e.g., Porter et al., 1974) are included in some definitions of commitment, but excluded from others and instead viewed as antecedents. Similarly, some definitions include aspects of motivation, behavioral intentions, or even behaviors within the definition of commitment, whereas other definitions exclude these concepts, instead viewing them as distinct constructs that result from commitment. The location of the construct boundary matters as, depending on the definition used, a measure is either valid or confounded, constructs redundant or distinct, and observed empirical relationships accurate or inflated due to construct and measurement overlap (Klein et al., 2014). Klein et al. (2009) argue that five of the eight categories of definitions they identified are problematic because of conceptual overlap with antecedents or consequences. The remaining three conceptualizations view commitment as an attitude, a binding force, or as a bond or attachment. Klein et al. (2009) further note that commitment is not an attitude as attitudes are currently defined, and make the case for commitment as a bond over a binding force. There is not as yet, however, agreement on this in the literature.

A second aspect of the conceptual debate is whether commitment is multidimensional. There are several frameworks that view commitment as multidimensional, but there appears to be consensus that commitment, at its core, is one dimensional (Becker et al., 2009), with the dimensionality debates more around the multiple targets of commitment (e.g., organization, supervisor, career) and whether/how they are structured, the multiple bases that can lead to the formation of commitment (e.g., identification, compliance), and the multiple mind-sets that can characterize a commitment (e.g., normative, affective). With regard to commitment mind-sets, the empirical evidence does not always support the TCM, with arguments made for there being anywhere from two to eight distinct mind-sets (Klein et al., 2014). A related issue is whether all of these mind-sets should be considered commitment. The Klein et al. (2012) reconceptualization, for example, in differentiating among types of bonds and defining commitment as a particular type of bond, eliminates the need for ancillary concepts such as bases and mind-sets. Given the above conceptual disagreements, it is not surprising that there are also questions regarding the proper measurement of commitment. One set of issues centers around whether an uni- or multidimensional scale is needed and the extent to which those measures are construct valid. Another issue is whether the same measure can be used across targets or if distinct measures are needed for each commitment target.

Differences in Commitment across Targets

Organizational commitment is just one of a multitude of commitments individuals hold within and outside of work contexts. Those work-related commitments could be to other organizations (e.g., unions, professional associations, client organizations), individuals within or outside the organization (e.g., coworkers, supervisors, suppliers, customers), groups (e.g., work teams), and various ideas and initiatives (e.g., values, goals, decisions, policies, change programs). Commitment to different targets has, in the past largely, been studied separately, with different researchers examining different targets in different literature, and commitment to these different targets viewed as distinct (Klein et al., 2012). There have been efforts to integrate the research on commitment across targets and both the TCM and the more recent Klein et al. (2012) reconceptualization view the construct of commitment to be the same regardless of target. Meyer and Herscovitch (2001) extended the original TCM to be applicable to other targets; Klein et al. (2012) redefined commitment in a manner that is equally applicable to any target and concluded that although commitments to different targets may serve different purposes, there is a generalizable and distinctive meaning common to all commitments regardless of context or target. That conclusion was based on observed similarities across targets in terms of (1) how it is defined, (2) how it develops, (3) its antecedents, (4) the processes by which it operates, and (5) its consequences.

Defining commitment in a target-free manner does not mean that the target does not matter or that targets are interchangeable – only that distinct constructs are not needed to reflect commitment to distinct targets. There are likely phenomenological differences between commitments to different categories of targets (e.g., entities vs individuals), and

variation across targets can be expected in terms of the exact manifestation and relative importance of the identified causes and consequences of commitment (Klein et al., 2012). The need exists to systematically examine the differences and interplay among targets, but such research has been difficult up until now due to the absence of a brief measure that is applicable and comparable across any target. The need also exists, for a logically meaningful and parsimonious typology for categorizing commitment targets. Examples of needed research across commitment targets include identifying how the relative importance of the antecedents and outcomes might vary across targets and whether there are systematic differences in the development, maintenance, or dissipation of commitment over time across targets.

Temporality

Commitment has often been viewed as static construct, yet as a psychological state, levels of commitment can ebb and flow. Commitment theorists have recognized that commitment is a process that develops over time, yet there has been surprisingly little research on that development process, variation in commitment within individuals over time, or the dissipation of commitment. In terms of the formation of commitment, there is a large body of cross-sectional research examining correlates of commitment that are likely antecedents, but relatively little longitudinal research examining the development of commitment as a process that unfolds over time. There is theory to guide such research, but the presumed mechanisms (e.g., attributions, trust, salience; Klein et al., 2012; Meyer et al., 2004), and other possible factors warrant further investigation. In addition to better understanding the formation of commitment, research on factors that may strengthen, weaken, or even eliminate commitment is needed as commitments do not simply develop and then exist forever and key factors in altering commitment may not be the same as those that initially facilitate the development of commitment. There are only a few studies that have examined within-person changes in commitment over time and even fewer looking at how and why employees once committed to their organizations became uncommitted. As a result, we know little about how the consequences of such dissipation of commitment on work attitudes, behavior, or well-being; or how those effects differ depending on the reasons for the loss of commitment.

Downsides of Commitment

Finally, greater research attention needs to be given to the potential 'dark side' of commitment. The literature has largely assumed that more commitment is better without sufficiently recognizing that the consequences of high commitment can be either positive or negative for the individual, the organization, or both. This issue has been previously identified (e.g., Randall, 1988), but unlike the work on escalation of commitment, research on organizational commitment has almost exclusively focused on positive outcomes. High commitment can potentially be detrimental when the target is problematic (e.g., an unethical organization, abusive supervisor, flawed strategy), or when commitment becomes so strong as to bias judgment and decision making. Negative outcomes may also occur when commitment results in an individual expending levels of time and effort on behalf of a target that are not sustainable without sacrificing other commitments and/or well-being. This relates to another understudied downside of commitment, conflicting commitments. Research suggests that individuals can simultaneously commit to multiple targets and that such commitments need not be in conflict (Randall, 1988). There are, however, limits on an individual's resources (e.g., time, attention) and conflict is likely to result when multiple commitments create incompatible demands. Additional research is thus needed on both over commitment and conflicting commitment.

Cultural Differences and Influences

Commitment research has been conducted in numerous countries and it appears that commitment is relevant across cultures, but many questions remain concerning whether there are cultural differences in how commitment develops, is experienced, and influences behavior. There is some research suggesting that commitment models and measures developed in the Western world transfer reasonably well when applied in other cultures. Others (e.g., Wasti and Önder, 2009), however, question those results and the largely used imposed etic approach. Qualitative research is probably needed to better understand what commitment means to individuals within different cultures rather than simply evaluating the transportability of existing models. At that point, and after revising our models if needed, other issues including the appropriate translation of items and measurement equivalence, and the effects of cultural and values and norms on the development and experience of commitment can be examined.

Conclusion

Commitment is studied across a wide variety of disciplines, suggesting that it is a fundamental concept for understanding human behavior. Within the study of organizational phenomena, commitment has been one of the most frequently examined constructs. As a result of that attention, great strides have been made in our understanding of the antecedents and consequences of commitment, but many questions warrant further investigation and clarification. A better understanding of commitment is of both scientific and practical importance to organizations and individuals alike, as changes in the nature of organizations and work have not mitigated the need for a committed workforce.

Organizational Control

Paul Thompson, The University of Strathclyde, Glasgow, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Although control can be seen as the essential problem of management, its treatment in mainstream organizational literature is problematic. It is frequently asserted that new competitive pressures and the enhanced demands of a service-oriented, knowledge-based economy meant that 'command and control' is no longer an option for successful business. Yet, while changes in types and levels of control have taken place, the weight of evidence is that most large organizations remain traditionally managed. In addition, it is often claimed that the contemporary locus of control has become internal rather than external, through the spread of normative controls or panoptic surveillance. Considerable problems remain, however, with the evidence on the extent of such practices and their effectiveness. Changes in the structure of the economy and corporations, however, have led to a widening of the scope of and greater hybridity in controls.

Mainstream Approaches: Ambiguities and Absences

As Pfeffer noted, "control is at once the essential problem of management and organization and the implicit focus of much of organization studies" (1997: p. 100). Yet there are wide disagreements as to its significance and substance. In mainstream models of organization behavior, control is treated, at best, ambiguously. Some standard textbooks simply do not have chapters on the issue. Systems theory is based on equilibrium and interdependence, and therefore it tends to assume goal consensus and downplays systematic conflicts of interest or identity in the employment relationship.

When control is discussed it is often alongside coordination. Any complex division of labor requires mechanisms to set goals, allocate responsibilities, and evaluate the effectiveness of performance. Coordination is a more neutral term than control and more compatible with an assumption of goal consensus. In this context, control tends to be treated as a *monitoring* device, with management's role to check progress, and ensure that actions occur as planned and to correct any deviation. The emphasis is on technical inputs and outputs in a self-adjusting system, performance standards, and feedback mechanisms.

Such emphases, however, can be misleading. Control often *is* present in mainstream approaches, it just is hiding in the shadows of something else. The key term used by Pfeffer was *implicit*. Texts that do have chapters with control in the title often pass over quickly onto other issues, such as job design, organizational structure, or leadership. In the first instance, debate is focused on designing structures that facilitate levels of control and coordination appropriate to types of work that require different levels of discretion and standardization. In the second, discussion of leadership styles, such as the classic polarity of authoritarian versus democratic approaches, constitute ways of discussing control, but do so through the language of influence and motivation.

A Break from Command and Control?

Reinforcing this ambiguity about whether control is necessary, the more practical management theorists continually have tried to abolish it or proclaim its imminent disappearance. From the human relations writers of the 1950s, with their distinctions between (bad) theory X and (good) theory Y, to the advocates of 1970s-style job enrichment and contemporary empowerment; control has been presented as destructive and out of date. The idea was that a high degree of autonomy over one's own work was a precondition for job satisfaction, and high productivity has been a cornerstone of organizational psychology (as captured in notions like self-efficacy). From the mid-1980s onward *necessity* was added to desirability. Influential articles such as by Walton (1985) declared that new competitive pressures and the enhanced demands of a service-oriented, knowledge-based economy meant that 'command and control' was no longer an option for successful business. We were moving from control to commitment and from rules to values as means of coordination. The future was empowered employees in self-directing teams, participating in and sharing responsibility for a wider range of decisions – more voice and choice at work.

A problem with such approaches is their aspirational nature and the subsequent tendency to conflate prescription and description. It is accepted across different perspectives that changes have taken place with respect to controls. In particular, there has been, through teamwork, increased involvement of employees in microlevel decision making about how to do their work – a form of democratized Taylorism (Adler, 1993). Much of this has been influenced by the importation of Japanese management techniques, repackaged in the 1990s as lean production. Although this sometimes has achieved high levels of productivity, continuous improvement, and quality assurance, most studies conclude that such methods are accompanied by intense surveillance, extensive standardization, and new forms of cultural or normative controls (see Graham, 2005). At a broader level, studies are consistent in showing that most organizations, at least in Britain and North America, remain traditionally managed and continue to take a low-trust, low-skill path to competitiveness. In the context of generally tougher times, marked by downsizing and delayering, many employees experience empowerment largely as a form of work

intensification. Firms are finding it harder to deliver on the kind of 'package' envisaged Walton, in which increased commitment and responsibilities would be offset by greater job security and other enhancements to the employment relationship.

Although companies are indeed seeking to enhance service quality and efficiency, they are also investing in new control systems to monitor the consistency and characteristics of those outputs. In services, generally there is ample evidence that organizations are scripting employee–customer interactions that previously might have been left to employee discretion (Ritzer, 1993), or specifying feelings rules for the mobilization of emotional labor (Hochschild, 1985). This emphasis on the body has been expanded in recent research on aesthetic labor, showing how some organizations are imposing standards of 'looking good and sounding right' in some service settings. Indeed, customers can be incorporated into control processes through mechanisms such as mystery shoppers and forms of feedback and evaluation. The redefinition of hospital patients or students as 'customers' can be used to initiate coercive evaluations of public sector professionals. Such employees increasingly are faced with audits and other forms of accountability to government bodies. Contrary to claims about inevitably enhanced autonomy in knowledge-intensive settings, the work of scientific and technical staff increasingly is subject to measurement and codification through the metrics and tools of knowledge management. Such trends are consistent with surveys showing that in many sectors levels of discretion are falling, especially among professional and expert labor.

What this discussion suggests is that mainstream conceptual frameworks are not only overoptimistic, but they are insufficiently robust to deal with changes in the *types* and *levels* of control. For example, it is perfectly possible to have increased operational autonomy for 'empowered' managers, existing alongside much tighter financial controls through targets and budgets.

Control: the Basic Building Block of Radical Organizational Theory

As Pfeffer (1997: p. 135) noted, those ambiguities toward the idea of control are in part responsible for the development of more critical perspectives on organizations. For a variety of radical theories, control is the core concept. Whereas mainstream perspectives treat control and coordination together, radical theorists argue that management performs a *dual* function in the enterprise. Managerial practices are a necessary means of *coordinating* diverse activities; however, they also bear the imprint of conflicting interests in the labor process; a conflict that reflects the unique nature of labor as a commodity. When capital purchases labor, it has only a potential or capacity to work. To ensure profitable production, capital must organize the conditions under which labor operates to its own advantage. But workers pursue their own interests for job security, higher rewards and satisfying work, developing their own counterorganization through informal job controls and output norms.

To resolve this problem and because they are under competitive pressure from other firms to cut costs and raise productivity, employers seek to control the conditions under which work takes place. Control is not an end in itself, but rather it is a means to transform the capacity to work established by the wage relation, into profitable production. This idea of the transformation of labor power into labor is taken from Marx and is the starting point of what has become known as *labor process theory* (LPT). Its adherents describe control as a set of mechanisms and practices that regulate the labor process. Edwards (1979) distinguished three elements in any system of control:

- direction and specification of work tasks;
- evaluation, monitoring, and assessment of performance; and
- the apparatus of discipline and reward to elicit cooperation and compliance

Such elements, however, may be best described as *detailed* control, in that they normally are connected to immediate work processes, whereas *general* control refers to management's capacity to subordinate labor to their direction of the production process as a whole. This allows for the recognition of tremendous variations in how detailed control is exercised. Such a model can even allow for employers giving workers significant discretion over tasks, as in semiautonomous work groups, *if* it maintains their overall control. Control also is not absolute, but, at least at the micro level, it is a contested relationship.

Strategies of Control: Debates and Disagreements

Radical perspectives have been conditioned by Braverman's (1974) argument that the twentieth century has seen the tightening of managerial control, primarily through the application of Taylorist and scientific management strategies. He provided an important corrective measure to the widespread view that Taylorism was a failed system, superseded by more sophisticated behavioral theories to be used for motivational and job design tools. But it is recognized widely that Braverman overestimated the dominance of Taylorist strategies and practices, and underestimated the varied and uneven implementation.

Nevertheless, because Braverman confused a particular system of control with management control in general, the question of *alternative strategies* was put firmly on the agenda. The best known is Richard Edward's (1979) model that is based on historically successive dominant modes of control, which reflect worker resistance and changing socioeconomic conditions. A nineteenth-century system of *simple* or *personal* control by employers exercising direct authority gave way to more complex *structural* forms with the transition from small business, competitive capitalism to corporate monopolies. The first of these forms was *technical* control, typified by the use of the assembly line, which can pace and direct the labor process. The contradiction for management is that it created a common work experience and basis for unified shop floor opposition. In contrast, a system of *bureaucratic* control embedded in the social and organizational structure of the

firm rather than in personal authority, offers management a means of redividing the workforce and tying it to impersonal rules and regulations.

In contrast, the other most influential model from Friedman (1977) eschews the notion of stages, preferring to set out ideal types or strategic poles of responsible autonomy and direct control, which run parallel throughout the history of capitalism. Paralleling mainstream notions of mechanistic and organic structures, or low- and high-trust employment relations, each strategy is said to generate its own inflexibilities in such areas as hiring and firing and task specification. The choice of strategy is governed by variations in the stability of labor and product markets, mediated by the interplay of worker resistance and managerial pressure.

Although the emphasis on alternative strategies was welcomed, such conceptual contributions were criticized by some commentators for the 'panacea fallacy' – that is, the idea that capital always seeks and finds definitive and comprehensive modes of control as the solution to its problems. Another strand of criticism drew from long-standing issues about the relations between ownership and management. Capital's interests are not given and management practices cannot be 'read-off' from them. Assumptions of a 'tight-coupling' underestimate the diversity and complexity of such practices and the significance for decision-making processes within the enterprise. In addition, there are conflicts within management, reflecting contending interests groups and the difficulty of carrying out integrative functions.

What has happened in practice is that researchers influenced by LPT have largely ignored such overarching frameworks and have used particular concepts, such as technical or bureaucratic control, to explain particular trends in new technology, recruitment practices, or internal labor markets. Alongside such usage, other researchers have opened up the empirical and theoretical terrain by demonstrating how control processes inside work or are shaped by the broader social divisions of labor connected to gender and family relations. LPT also has attempted to develop a more complex framework that can deal with the tensions between different management levels, functions, and ideologies in framing and exercising control. The most innovative is associated with Armstrong's (1989) work on *interprofessional competition*. Management functions for capital are mediated by competition among occupational groups to become the trusted agency to carry out control functions. Armstrong charted the historical and contemporary forms of competition between engineers, personnel, accounting, and other professions within the business enterprise. Who comes out on top is a function not just of their power resources, but the societally specific constitution of managerial expertise (for an overview of such research, see Thompson and van den Broek, 2010).

New Challenges, Critiques, and Responses

Although a degree of common ground emerged both about the varied influences on control strategies and the variations in combination and context through which control is exercised, new challenges have arisen from critical readings of contemporary social and organizational changes.

The Locus of Control: From External to Internal?

Rather than denying the salience of control, new challenges were made concerning where and how it was taking place. What was discussed earlier as a move from control *to* commitment was instead seen as a form of *internal control* that does not rely on external rewards and sanctions, or rule-following. Outside the largely consensual corporate culture literature, theorists within a labor process tradition already had gone someway down this route. Burawoy (1979) had shown how employee participation in production games and workplace rituals generated consent to existing social relations, constituting workers as individuals rather than as members of a class. In other words they 'helped' to control themselves. Later, Ray (1986) argued that control by corporate culture was the last frontier, in that it had enabled organizations to generate sentiment and emotion, simultaneously internalizing control and linking personal with corporate identity.

A further twist to such arguments has come through more recent influences from Foucault and poststructuralism. At the height of the attention paid to corporate culture in the early 1990s, theorists accepted the intent and outcomes of managerial action but redescribed it in critical terms, referring to the closing down of rival cultural spaces and the production of 'designer' employees (Casey, 1995). The specifically Foucauldian influence can best be seen in some influential accounts of changes in factory work. Sewell (1998) claimed to have identified a new model of labor process control that counters the optimistic gloss of the empowerment and teamwork literature, while moving beyond the confines of traditional LPT. 'Panoptic' forms of control augment existing practices through the interaction of 'vertical' electronic surveillance and the 'horizontal' dimension of peer group scrutiny within teams. Sewell made much of the enhanced capacity of management to collect, display, and attribute performance data. With respect to teams, he relied on other cases, including McKinlay and Taylor (1996) to make a case for horizontal control. Here, team members create the intersubjective conditions for compliance by creating disciplinary rules within delegated authority, thus collaborating with management to identify and reward the 'good worker.'

The implication of Sewell's argument is that such a combination solves the 'control-engage' dilemma identified by LPT and suffered in different ways by generations of managers. The new techniques allow management to rationalize knowledge and work, but not through obtrusive Taylorist and bureaucratic means, while mobilizing and manipulating the subjectivity of employees. The rapid growth of call centers and automated call distribution systems also provided plenty of scope for Foucault-influenced commentators to reinforce a focus on the increased surveillance potential of the electronic panopticon. Some commentators became convinced that the call center represented the ultimate and total control system. The capacity of the computer monitoring

screen to not only direct tasks, but to get inside the heads of Customer Service Representatives (CSRs) rendered supervisory power both 'perfect' and its actual use unnecessary.

Although the focus on culture change has faded in tougher times, poststructuralist writers have continued to highlight the significance of identity in exploring the continuance of normative controls through managerial discourses; human resource management practices, such as induction, training, and promotion (Alvesson and Willmott, 2002); and the more recent emphasis on employees 'living the brand.' It is argued that such approaches are particularly pertinent in knowledge-intensive firms where employees are not amenable to direct or task-based controls. McKinlay has argued that "[t]he primary means of managerial control of knowledge work is the regulation of employees self rather than work flows or task" (2005: p. 245).

Changes in the terrain and frontier of control take place continually, and it would be difficult to deny that *some* shift toward electronic and self-surveillance has taken place in *some* industries. Similarly, while explicit culture change programs may have gone out of fashion, increased attention does seem to have been placed in *indirect* forms of control that would include the use of intensive recruitment methods. In putting more effort into recruiting the 'right people' with compatible attitudes and orientations, there would be less need for direction of work tasks.

A range of objections can and have been made, however, to these twists on accounts of organizational control (Thompson and Ackroyd, 1995). Few of its enthusiasts adequately consider issues of time, place, and people – in other words, the generalizability of such controls outside of the high-tech, strong culture firms from which the evidence largely comes. The central problem, however, is the confusion of the formal capacities of technological and managerial systems with their actual usage and effectiveness. This is compounded by a tendency to draw evidence primarily from managerial sources, underestimating the capacity of labor to find individual and collective spaces to dissent or resist. Discourse and identity writings are still light on actual evidence of high commitment and internalized corporate norms (Leidner, 2006). In cases in which these problems are considered more fully, as in the McKinlay and Taylor case study of an electronics plant in Scotland, a more rounded and complex picture of the gap between intent and outcome is revealed. Finally, it is not only debatable how internal*ized* the new controls are, but also how *internal*. Normative rules in strong culture companies may be different from traditional task-based control, but they still are rules. Management's sources and use of information may have increased, but there is little evidence that is unobtrusive or regarded by employees as objective and unconnected to visible authority relations. This is strongly confirmed in most research on call centers. Most studies show that employees are able and willing to question the purposes and accuracy of 'the stats' and to find ways to both evade some of the pressures of call monitoring and locate blind spots in the system.

One of the problems with shifting locus arguments is the implication that shifts are substantive, if not permanent. Given the highly dynamic nature of the frontier of control, it is equally possible that traditional controls may reemerge, albeit in some new forms. This is what appears to be happening as large organizations in the private and public sectors are subject to heightened competitive and financial pressures. Performance management appears to be an increasingly central focus of managerial attention. It is unusual for most employees not to be faced with a plethora of targets, key performance indicators, and related controls in the context of external and internal restructuring and cost pressures. In increasingly 'lean' environments, tighter and more pervasive systems of monitoring and surveillance, supported by more visible accountability and stringent disciplinary procedures are more common.

The previous era partial shift to consent making may have been eroded by the principles and practices of 'market rationalism' in the context of shareholder-driven economic pressures. Normative interventions promoting commitment and cultural change are being marginalized (Kunda and Ailon-Souday, 2005). Compliance rather than commitment may suffice in circumstances in which organizations and their workers are subject to enhanced market discipline and insecurity (McGovern et al., 2007).

Questioning the Centrality and Scope of Workplace Control

Traditional controls may persist, but another kind of locus argument has been raised by recent research. Models such as those associated with Richard Edwards conceptualized developments largely in terms of managerial strategies within large companies pursued at the workplace or plant level.

Friendly critics of LPT always raised questions as to whether the centrality given to control of labor is actually reflective of managerial behavior. It was argued that we cannot view management strategies and tactics primarily from the vantage point of the labor process. If anything, managers are dominated by problems of the outcomes of that process, including sales, marketing, supply, and cash flow. The concept of *the full circuit of capital* is used to argue that we must be concerned not only with the *extraction* of surplus value through controlling the labor process, but its realization through the sale of commodities, as well as the prior purchase of labor.

It was widely accepted within LPT that some of these objections were a necessary corrective measure to a debate that often had lost sight of the role the broader political economy because of the emphasis on *management* control. Such concerns have been amplified by more recent developments signaling a move away from managerial capitalism and the emergence of a more financialized economy with more complex, fluid interorganizational relations that raise issues about the changing nature of the workplace. Contemporary organizational and employment structures often are dispersed and disaggregated. Controls thus operate at an interorganizational level, across conglomerates, production networks, or supply chains. Some traditional analytical tools are ill-equipped for understanding this. A good illustration of these complexities is the retail supply chain. Prominent examples such as Wal-Mart illustrate retailers' growing ability to transfer risks and costs to suppliers, and to exercise controls indirectly or directly over aspects of their operations. This is facilitated by investment in retail technology and information technology systems that enable retailers to manage and monitor information and goods within the overall supply chain.

Supply chains are just one form of more complex interorganizational relations. As corporations get larger, their activities become more diverse, and their goals become more shareholder driven, such 'directed' networks exercise significant power at the center that constrains unit autonomy (Ackroyd, 2002). Studies report a transfer of powers from local, unit-level managers to corporate executives who are more directly accountable to shareholders. Managers are under continual pressure to cut labor costs and restructure operations to meet capital market requirements (Appelbaum et al., 2013). This adds up to a strengthening of financial control systems across a variety of organizational boundaries. Information and Communications Technology (ICT) systems facilitate the capacity of corporate management to operate sophisticated surveillance mechanisms and resource allocation models. These frequently lead to a cascading down of monitoring and target setting for performance measures that tighten controls for both managers and workers alike, albeit in different ways.

Some researchers argue that new loci for value creation and decision making challenges work-based control perspectives traditionally favored by LPT and employment relations scholars. Reedhas made a similar point: "The major focus of control has moved away from the design and monitoring of standardized work tasks toward the management of highly complex informational, human and material 'flows'" (2010: p. 42). These are important points, although LPT already has been moving away from workplace-centric control models. It also is the case that the centrality of labor costs within restructuring and value creation means that broader changes are highly likely to have consequences for workplace controls.

Conclusion

Management always may be looking for the final frontier, but like the crew of Star Trek, they never really find it. This is hardly surprising. Conflicts of interest and constraints of circumstance run too deep. A close examination of contemporary organizational trends and their analysis reveals considerable continuity in theory and practice. Just as newer normative controls do not necessarily replace traditional task-based ones, extraworkplace mechanisms add to rather than displace intraorganizational forms. Sometimes theorists are describing the same practices in a different conceptual language. Electronic surveillance can look remarkably like Edward's concept of technical control; the exaggerated claims for empowerment strongly resemble those made for work humanization in the 1970s. Willing internalization in one framework can impose normative controls in another. It would be foolish to claim that nothing changes. Emphases within the repertoire of controls change, particularly as the wider structure of economy and society is transformed. Broadening the scope of controls in the new interorganizational landscape is a prime example. Reed (2010) has attempted to sum up these trends by referring to new control logics – complex, multilevel hybrids that combine the hard and soft dimensions from electronic surveillance to cultural engineering and performance management. Nevertheless, while work remains a contested terrain, there will be a frontier of control. For example, changes in the labor force and broader cultural norms can bring new problems, such as the rising tide of sexual misbehavior at work. In turn, this creates the conditions for new controls, such as codes of conduct that specify appropriate boundaries of behavior and what sanctions might follow if they are transgressed. It is the task of organizational analysis to explain the character, combination, and circumstances of that changing frontier.

Abstract

Anthropologists have studied organizations since the 1930s. In the 1980s, anthropologists' concepts of culture were instrumentalized by nonanthropologists to promote 'organizational culture' as a management tool. In subsequent decades, concern shifted to welding employees from different 'national cultures' into transnational corporations and organizations concerned with international governance. In such organizations, anthropology graduates are increasingly employed as 'cultural experts.' We track the anthropological research on organizational culture and argue that the sensibilities and analytical skills acquired and the concepts developed through the ethnographic encounter gives anthropology a unique voice in the study of cultural matters in organizations.

Introduction

'Organizational culture' came into vogue as a management tool in the late 1970s. Anthropologists had been engaged in research on industrial and other organizations since the 1930s, but these studies took a new turn when managers, consultants, and organizational researchers drew on anthropological concepts of culture in the process of devising and managing the culture of their organizations. Anthropologists found their analytical concept of culture was implicated in the phenomenon they were trying to study empirically. Anthropologists try to maintain a distinction between their own analytical (etic) concepts and the (emic) concepts used in the everyday life of the people they study, whereas now they found the emic and etic were entwined.

This article will focus on anthropological studies of 'organizational culture' as a tool of management and a *raison d'etre* for organizations. The first section gives a brief history of anthropological approaches to organizational culture. The second section outlines the rise of 'organizational culture' as a key management concern. It considers the 'Japanese connection,' the advocates of 'organizational culture' in the United States, notably Peters and Waterman, and Schein, and the further transition into 'values-based management.' We explore how exponents of these approaches to management drew on concepts and understandings of culture that were often at variance with contemporaneous anthropology. The third section addresses managing culture in transnational corporations and the fourth section concerns working with culture in organizations that are engaged with international governance, notably the European Union, which tried to develop a 'European culture,' and the United Nations Educational, Scientific and Cultural Organization (UNESCO), which engages with multiple concepts of culture in preserving cultural heritage and promoting a 'culture of peace' in the world. The final section sums up the argument by emphasizing the critical use of anthropological concepts and strategies in organizations. This is especially important given that employment in organizations as 'cultural experts' is a growing field of work for anthropologists.

Anthropological Approaches to Organizational Culture

It is common to date the beginning of anthropologists' involvement with industrial organizations to the Hawthorne Project (1927–32). This project was led by Harvard psychologist Elton Mayo and challenged Taylorist management strategies by arguing that managers should take into account the emotional needs of employees, including their need to belong to a group or a team. He knew two prominent anthropologists, Radcliffe-Brown and Malinowski, and one of Malinowski's students, Lloyd Warner, was involved in designing and carrying out the observations. Those studies were taken further by British anthropologists who employed participant observation in a series of shop-floor studies in Manchester in the 1950s and 1960s (Wright, 1994: 6–13). They explored in great detail the strikingly different ways that workers organized themselves in comparable factories. Drawing on the Manchester School's sophisticated analyses of conflict, notably in sub-Saharan Africa, these studies generated a range of analytical concepts for a much more nuanced understanding of the class conflicts that marked British industrial relations at the time.

In the Hawthorne factory studies, anthropologists tended to take the managers' rationality as a given and 'study down.' Perhaps even more than in the colonies (Loizos, 1977), they investigated the everyday life and ways of thinking of the workers in order to explain these to managers (Wright, 1994: 8). The Manchester shop-floor studies adopted some of the radical promise of modern anthropology, by presenting workers' ways of organizing themselves as rational and worthy of respect, even if not in accord with those who managed and governed them. But it was only in the 1970s that anthropologists turned their attention to studying the elites themselves, their ways of governing or managing, and their claims to define 'culture' for those they governed. A surge in studies of nationalism explored the ways that elites invented national 'traditions' (Hobsbawm and Ranger, 1983) and as Gellner (1983) put it, constructed a political and symbolic formation that gathered one people, one ethnicity, with a common language, shared attributes, and sense of belonging under the one

'political roof' of a modern nation-state. This focus on the *constructed* nature of national culture coincided, in England at least, with an emerging middle class among descendants of postwar migrants and new immigration from a worldwide movement of people from the global south to the global north, including a diasporic intelligentsia. This indigenous and imported black and Asian middle class unsettled the English elite's assumption that they had the right to define national culture and the age-old canons of "the best which has been thought and said in the world" (Arnold, 1869: viii). Just at the moment when this emergent force claimed that everyone had the right to contest and contribute to the core concepts of Englishness, management studies developed the idea that a managerial elite could devise a company's culture, as a set of values and behaviors that they would expect all workers to share and demonstrate in their daily work culture as a top-down and uncontested tool of management.

By the 1990s and into the new century, there were four major meanings of 'culture' in play. First, national culture was projected as a shared history, common adherence to key institutions and symbols, similar ways of behaving and communicating, and a sense of belonging. Although moments of crisis (for example, the Rushdie Affair, Asad, 1993) exposed the work of elites in maintaining this construction, their success was evident in the popular assumption that it was natural – even God-given – to see the world as made up of such nation-states. A second notion of culture focused on 'communities' in smaller localities or 'subcultures' of ethnic minorities, working class, or youth. Largely dismissed by anthropologists, but still used widely by politicians, in the media and in everyday discourse, this idea of culture portrayed members of a 'community,' 'people,' or 'subculture' as homogeneous, as if any member could be 'known' by a checklist of characteristics and as if they uniformly and unchangingly shared the same values and ways of behaving. Third, and in contrast to both of the meanings above, in a new approach in anthropology and cultural studies, culture was no longer seen as consensual but as a site of contestation. Within any nation or community, there would be a political struggle between different individuals and interest groups over who had the power to define the core characteristics of a culture, how other individuals or interest came to be dominated or subsumed, and with what material consequences (Wright, 1998a). Fourth, as we will see below in the discussion about UNESCO, a pluralist view of everyday life conceived of individuals or small groups migrating and living in a variety of 'mixed communities' in the course of their lives. In the process, they collected ideas, values, and ways of living from multiple sources, from which each assembled an idiosyncratic bricolage. In this view, culture is not shared and predictable, but negotiated and contested in a continual process of creation.

It was especially the first two concepts of culture that appealed to management and came to provide a fragile and ambiguous connection between anthropology and the world of business. Notably, a single quotation from the anthropologist, Clifford Geertz, was to be found in numerous management publications and consultants' power points:

> Believing, with Max Weber, that man (sic) is an animal suspended in webs of significance he himself has spun, I take culture to be those webs, and the analysis of it to be therefore not an experimental science in search of law but an interpretive one in search of meaning.
> Geertz, 1973: 5

The article from which this is drawn analyzed how three people involved in an incident had very different understandings of a sequence of actions. Geertz showed that each was weaving a different web from the same threads and each had different structural power and personal ability to impose their meaning on the others, with the dominant one accruing substantial material outcomes. This view of culture as a political and contested process is akin to the third meaning of culture above. Yet in management studies, this quote was used to argue for managers' generating a single vision for the organization, implemented from the top, so as to align all the informal structures and practices of all the departments into one 'web of meaning' or corporate culture. This smacks of the second meaning of culture, and was precisely the meaning of culture that Geertz was writing against. Anthropologists found their concepts used in management in such disconcerting ways. As George Marcus put it: "For anthropologists especially there will be a particular irony in this migration of their signature concept appropriated and transformed in a sphere of their own society quite foreign to them — that of business — and without any consultation or credit either" (Marcus, 1998: 8). In the 1980s, when the culture concept (in the second sense of shared values and behavior among a group of homogenous people) was just becoming the greatest conceptual export success in the history of anthropology, anthropologists had already turned their backs on it. The problems and dangers of the politicization of the culture concept have received so much attention within anthropological discourse (Wright, 1998a) that some discarded it as an analytical tool altogether (Abu-Lughod, 1991).

The Rise of 'Organizational Culture'

The Japanese Connection

It was the staggering Western economy compared to impressive Japanese growth rates that initially sparked the interest of Western firms in establishing 'corporate cultures.' In his business bestseller from 1981, *Theory Z. How American Business Can Meet the Japanese Challenge*, the Japanese-American organization researcher William G. Ouchi (1981) argued that the deepest reason for the Japanese *Wirtschaftswunder* was not technological inventions or tight financial policy. The root cause was the Japanese culture: what characterized Japanese companies was the loyalty of their employees and the close social relations between colleagues. Contrary to Weber's (1947) idea that bureaucracy was built on the absolute separation of the personal from the professional, according to Ouchi, in Japan, the personal and the professional met in a sublime and productive synthesis. Such depictions of synthesis between national and individual 'character traits' in Japan have a long legacy, starting with Benedict's (1946) treatment of Japanese wartime ideology as the depoliticized and ahistorical cultural characteristics of the population. For Ouchi, the Japanese tradition to be personally involved in the workplace was founded in an unselfish discipline, which is

rooted in traditional Japanese virtues of 'intimacy' and 'trust' (Benedict, 1946: 9). The implication of Ouchi's study for the West was, of course, that the desired corporate culture (in the second meaning of culture, above) was not isomorphous with national culture (in the first meaning, above) and thus did not grow organically from existing social forms. If the Japanese growth depended on an essential 'Japaneseness,' then how could it be transmitted? How could Western business leaders learn from it? In Europe and the United States, corporate culture had to be a 'project'; organizational culture had to be engineered.

US Corporate Culture

In the beginning of the 1980s, a number of influential US business bestsellers appeared. They all argued that organizations were not driven simply by concerns for hard-line efficiency, but should rather be seen as collective worlds governed by values and meanings (Peters and Waterman, 1982: 56, 61). Peters and Waterman's bestseller *In Search of Excellence* argued that the recipe for company success was a corporate culture. Managers and consultants started to pay attention to their organizations' collective identities: they developed symbols, enacted rituals, and identified corporate cultures to motivate and inspire employees (Deal and Kennedy, 1982; Morgan et al., 1983). Culture also became an important part of the curriculum in management studies, be it human resource management or cross-cultural management.

In organizational studies, Edgar Schein is the doyen of organizational culture and his influence can hardly be exaggerated. His book *Organisational Culture and Leadership* (1986) is probably the single most important book in the research field and has inspired both managers and other researchers working with 'organizational culture.' Schein's relationship to anthropology is ambivalent. On the one hand he draws a contrast between his own 'clinical-consultant' approach to organizational culture and the ethnographer's participant observation (Schein, 1992(1985): 47–48). On the other hand he draws on the "complex notions of culture of anthropologists" (Schein, 1992(1985): 3) and their ability to 'find' and 'uncover' culture in people's everyday lives to mark himself off from 'culture-vulture'-consultants and their account of organizational values as something that can be readily invented by managers and implemented in organizations. Instead, he develops a three-tiered model of culture as 'artifacts,' 'espoused values,' and 'tacit assumptions,' putting his greatest emphasis on this last level of unconscious 'basic underlying assumptions.' It is this last level that defines his celebrated conception of culture as

> a pattern of shared basic assumptions that the group learned as it solved its problems of external adaptation and internal integration that has worked well enough to be considered valid and therefore, to be taught to new members as the correct way to perceive, think, and feel in relation to those problems.
> Schein, 1992(1985): 12

Schein's insistence on using 'complex anthropological notions' rings a bit odd, though, as this conception resonates with the homeostatic models of culture (the second idea of culture, above), which most anthropologists had left behind before Schein wrote his book. Schein's ideas of organizational culture as a set of fundamental assumptions that guide behavior and are reproduced between generations of workers seem empirically implausible in large organizations, where people occupy different hierarchical positions. They are even less credible in today's turbocharged labor markets, where people change jobs and organizations with increasing frequency (Krause-Jensen, 2010: 56–68).

It is quite curious that one of the most widely read and classic examples of an ethnographically grounded analysis of organizational culture that chimes with the third anthropological approach to culture (above) was authored by one of Schein's students, Gideon Kunda (1992). In the 1980s, he did a detailed study of the corporate culture project of a US-based Hi-Tech firm, 'Tech.' Kunda analyzed the company's efforts to instill a corporate culture as an example of soft normative control, and he drew on a range of theories, including about ritual, to understand how corporate culture was communicated, what interests and ideas lay behind it, and how members responded to the efforts. The main ethnographic site of his fieldwork was the engineering division of the company, which pointed to the double entendre of the book's title, *Engineering Culture*. What people came to share was not a corporate culture, but an ambivalence about their involvement: the harder the company tried to engineer its culture and propagate organizational ideology through seminars and corporate newsletters, the more the members responded with resentment and cynicism. Their sense of self as engineers – their own 'engineering (sub)culture' – grew from their collective if discreet dissociation from the espoused corporate culture.

Value-Based Management

As described above, the notion of culture has been central to human resource management as a relay between the individual and the organization. The central aim behind establishing an organizational culture is to make a bridge between employee concerns and aspirations, and the strategic aims of the organization. Kunda and Van Maanen (1999: 65) argue that there used to be a cultural contract or social understanding behind the 'corporate culture project': "Loyalty in return for a career, commitment in turn for an identity, dedicated performance in return for meaningful work." However, since the 1980s, continuous waves of reengineering, downsizing, and outsourcing have seriously challenged the premises on which this contract rested. With an increasingly mobile labor force, the project of training every employee in the corporate culture through away days and training camps became too expensive.

In his book on the Danish company Bang & Olufsen, anthropologist Jakob Krause-Jensen traced how the word 'culture' largely vanished from the organizational strategies and was supplanted by 'value-based management.' This new concept continued the company's attempts to align individuals with corporate strategies. Krause-Jensen explored the semantic shifts involved. 'Culture' fell out of favor because it carried cumbersome connotations of tacit understandings and norms slowly accumulated through stable communities living and working together. This idea was out of synch with the conditions of flexible capitalism. 'Values' did not imply socialization in the same way as culture. Belonging to the realm of ideas,

values were easier to disseminate. High-ranking managers and consultants identified the fundamental values of Bang & Olufsen as 'poetry,' 'synthesis,' and 'excellence.' They claimed to have 'discovered' the organization's inherent values, rather than inventing and imposing them. They therefore expected these values to percolate through every aspect of the employees' working lives and to resonate with the consumers. Previously, 'corporate culture' had been the domain of the human resources department, whereas the marketing department joined in the project to identify and promote the company's values as part of establishing the corporate brand. Within the organization, however, this project did not achieve the aim of creating a common platform of shared values. No sooner had the values been excavated and highlighted than employees in different departments began to contest them or dismiss them as too remote from their working reality.

Managing Culture in Transnational Organizations

Global capitalism has spurred another strategic interest in culture in organizations. The growth of multinational organizations has been accompanied by attempts to understand and manage national cultural differences within them. A particular and very influential way of conceptualizing and working with national cultures in organizational studies can be seen in Geert Hofstede's *Culture's Consequences* (1984). Hofstede used questionnaires distributed in the sales organizations of IBM in the 1970s to classify different nationalities along five value dimensions that he calls "power distance, uncertainty avoidance, individualism, masculinity, pragmatism and indulgence" (http://geert-hofstede.com). According to Hofstede, culture should be understood as the 'collective programming of the mind' (1984: 25). Although the book challenged the idea that American management practices could be implemented unproblematically across the globe, anthropologists will find many reasons to question its methods, and challenge its concepts and conclusions. Hofstede's approach and view of national culture as an immutable essence that can be isolated, measured, and condensed into a limited number of values clashes with some basic convictions of most fieldworking anthropologists for whom thoughts and practices cannot be properly understood outside the context in which they are situated.

Anthropologists have developed understandings of national differences and how they are articulated in transnational organizations that are very different from Hofstede's. In the 1990s, Swedish anthropologist Christina Garsten did a multisited ethnography of Apple Inc. Through fieldwork in three different sites – Stockholm, Paris, and Cupertino, where Apple's headquarters are located – she analyzed how the company attempted to mobilize employees through defining itself against the titans of the industry like IBM. They projected an image of themselves as a transnational corporation with a coherent identity marked by a countercultural zest, lightness, and entrepreneurialism. This study is an example of how a very strong corporate culture is modulated, ironically embraced, or differently interpreted in national subsidiaries at various distances from the corporate center.

Anthropologist Tomoko Hamada also developed an approach quite different from Hofstede's when she analyzed how national cultural differences are played out in a US subsidiary of a Japanese company. Literally an 'extended case study,' she described events surrounding a sexual harassment lawsuit from the standpoints of the various people involved. The point of her analysis is that national differences were important, but certainly not the only relevant distinctions in the organization. Class, gender, and race were equally important and the participants' perceptions of their national differences underwent decisive changes as the case developed.

A third example is Galit Ailon's (2007) study of a successful Israeli-American Hi-tech merger. She directly challenges Hofstede's ideas that every nation is regulated by an essential set of values. Through detailed descriptions of everyday work life, the book shows how the Israelis' sense of identity is not *a priori* but is sparked by encounters with the American merger partners. She treats national identity as "a symbolic resource that assumed a potent role in the social production of a *sense* of difference," rather than an immutable essence (Ailon, 2007: 138).

Working with Culture in Transnational Organizations

The notion of culture has also played a crucial role in organizations concerned with inter- and supranational governance. Anthropologist Cris Shore (2000) has studied the European Commission's attempt to create 'ever closer union among the peoples of Europe.' Crucially, this has involved trying to create a public or political community with a common sense of belonging to 'Europe.' To overcome the 'democratic deficit' and build the cultural bedrock of such a democratic regime, the Commission engaged in a range of cultural policies. These aimed at transferring popular loyalty from the nation-state and engineering a love of Europe as a *patria* and a European consciousness in people's everyday lives. They tried to generate an idea of a shared European heritage and common contemporary culture through the creation of a flag, an anthem, European statistics, EU citizenship, and a common currency, with banknotes and coins designed as icons and symbols of new Europe. Simultaneously, they tried to forge a sense of Europeanness among the national civil servants appointed to the Commission. It was expected that, by working together, there would be an 'enmeshing' (*engrenage*) of the European elites: they would shift their ideals and loyalties to build an integrated system of public administration and a supranational institution that would become the custodian of the European ideal. However, in practice, a system of informal networks, patronage, and backdoor recruitment developed, until an investigation found an 'organizational culture' marked by widespread fraud, mismanagement, and endemic corruption.

UNESCO has no such problems with legitimacy: it is known as the intellectual arm of the United Nations system and its Conventions and Declarations wield considerable moral authority among member states. With its overordinate aim to foster world peace, UNESCO uses the same key concepts of culture to order both its internal operations and to mobilize its participants throughout the world. But the meaning of 'culture' has gone through several transformations (Nielsen, 2011; Wright, 1998a,b). Initially, the conception of culture was like Arnold's, as the canon of great art and architectural and archaeological monuments with universal value, which would be disseminated by an intellectual and political elite through

UNESCO. Instead of being linked to national identity (as in version 1 above) in the founding charter, culture was seen as a universal route to human perfection. Culture would "alter … the minds of men," create "intellectual and moral solidarity" and shore up peace. In the 1990s, there was finally a shift to a demotic idea of culture, but organized in 'archipelagos' (Eriksen, 2001), with each 'people' having its own culture (as in version two above). Now the promotion of cultural diversity, respect for difference, and the rights of minorities would be the route to peace. However, this relativism was tempered by an implicitly Western normative judgment that some cultural practices, like genocide or honor killings, should be condemned (Wright, 1998b: 179–180; Nielsen, 2011). Cultural diversity soon morphed into the fourth, pluralist, idea of culture. With the global flows of people, images, ideas, and goods, everyone should be able to enrich their lives by choosing and mixing elements of their own and others' cultures. Culture comes to be seen as a creative capacity in the hands of people themselves, a dynamo for change, a source of freedom, through which individuals can respond with imagination and vision to changes in the world. Successful development would be evidenced by a 'flowering of culture' (UNESCO, 1996) and a world 'culture of peace.'

Each of these transitions is the culmination of long processes of contestation over the meaning of culture (as in version three, above), but new meanings are never closed and final; the older meanings are always available and kept in play. Where in UNESCO do these contests over the organization's meanings of culture take place? Nielsen's (2011) study of the UNESCO bureaucracy shows that this is not the site of such contestation. A successful UNESCO bureaucrat is one who writes documents by sustaining the ambiguity of keywords like diversity, creativity, tolerance, freedom, and culture (Nielsen, 2011: 282). Bureaucrats take care not to define or dislodge the precarious meanings of 'resource-generating key words' like 'culture of peace,' which are at the center of projects reliant on member states for funding (Nielsen, 2011: 284). Instead, bureaucrats assemble meetings of academic 'experts' and nongovernmental organizations to present and discuss contested ideas of culture. It is in the regional and world conferences to develop new instruments of governance, for example, on Cultural Diversity or Intangible Cultural Heritage, that these contestations over the meanings of key words come to a head, not least in the all-night sessions where government delegates draft an Action Plan or a new Convention (Wright, 1998b). The major project led by Bendix et al. (2013) shows that as soon as a Convention, such as that on Intangible Cultural Heritage is ratified by a state, a whole new assemblage of actors – governmental, nongovernmental, commercial, professional, and community – begin to contest the ways that particular concepts and instruments will be used in a specific context. Their study traces who gets to define UNESCO's meaning of culture, for whom, and with material consequences, in places far distant from UNESCO's Paris headquarters.

Conclusion

These analyses of organizational culture do not result in a checklist of the key characteristics of an anthropological approach (we are not trying to turn anthropology itself into a culture *à la* version two above). However, it is possible to identify some family resemblances, which have grown out of anthropology's disciplinary legacy of cultural critique and its ethnographic methodologies.

As demonstrated above – with the risk of exaggerating a bit – it is possible to distinguish anthropology (with its concomitant ethnographic research strategies) from mainstream perspectives on organizational culture (Gellner and Hirsch, 2001; Ybema et al., 2009). A major difference is that much nonanthropological description of culture shares an appetite for 'how to,' which often leads to treating culture and values as 'variables' that cause or regulate behavior in uniform ways. There is a huge difference, however, between the lived experience of working in organizations, with their ambiguity and confusion, and the tidy management texts and reports on 'organizational behavior.' A major tenet and ambition of anthropology is to capture those experiences and understand them in the context in which they are situated.

The anthropologists who study organizations ethnographically try to get behind the common sense and official, managerially sanctioned worldviews often implied in the ideas of 'an organizational culture.' Such notions would often emphasize convergence, sharedness, similarity, and normative consensus. Anthropologists, on the other hand, do not assume consensus and regard sharedness as an empirical question. Researchers in organizational behavior tend to see organizational culture and values as the description of a deeply sedimented, communal identity, whereas anthropologists regard it as an often ambiguous and contested social accomplishment tied to particular (managerial) interests. As a consequence, anthropological/ethnographic analysis of organizational culture will often be in the form of a 'thick description' rather than distilling 'factors' and isolating 'variables' to predict outcomes. An important undertaking for anthropologists and ethnographers who work with organizational culture has been to look into the ideas and the practices surrounding culture projects and to do a cultural critique (in the enlightenment sense) of the culture concept and the way it has been understood and put to use in organizations and among management researchers.

A growing number of anthropologists work in organizations outside academia. They are sometimes employed in a consultant role as 'culture experts' able to grasp the otherwise intangible workings of the organization. Currently, many anthropologists are also employed in organizations as 'cultural experts' in another sense. Through their ethnographic methods they are expected to be able to uncover consumer culture: to identify customers' social aspirations and the contexts within which they use products. In particular, anthropologists are finding employment in user-based design from General Motors to Xerox's copying machines (Cefkin, 2009: 4–5). Previously, the concept of culture was largely used by consultants from a nonanthropological background, whereas now, anthropology graduates are employed to use the concept themselves in organizations. Such anthropologists face on a daily basis the challenge of using and developing 'culture' as an analytical concept to gain a distanced and critical purchase on the way ideas of 'culture' are used ethnographically in the management and everyday life of organizations.

Organizational Decision Making

Anna Grandori, Bocconi University, Milan, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Theory and research of organizational decision making (ODM) is organized in two parts: grouping contributions mainly concerned with the 'logic' and the 'politics' of ODM. Within each, the analysis develops in three movements. First, it points out how some classic 'divides' marked the field's origin, in relation to how uncertainty and conflict of interests may be dealt with. Second, it traces the key subsequent developments showing how the various models can be positioned on an ideal 'continuum.' Next, more recent works and research in relevant and related fields are considered, highlighting how they would allow to go beyond those classic continua and to indicate responses to increasing uncertainty and conflict implying 'stronger' rather than 'weaker' forms of thought.

Introduction

The field of organizational decision making (ODM) is not easy to define. As to the 'organizational' qualification, those who engaged in a conceptual definition have usually contrasted it with individual decision making, as ODM entails multiple individuals – whereby issues of communication and conflict may arise – and multiple occasions over time and matters – thereby excluding one-shot decisions among unrelated players – and have usually conceived it as decision making occurring 'in organizations,' intended as entities. However, those definitions are in many ways too narrow, with respect to both conceptual consistency and correspondence to the ODM actual empirical research tradition. In fact, to start with, any decision-making entity can be conceived as 'unitary' or not depending on the purpose of analysis. Individuals may not be such a unitary unit of analysis as often taken for granted: There can be conflict between objectives and 'multiple selves' also within an individual (Elster, 1985). Conversely, a multiperson system may be conceived as a unitary actor, if on a problem at hand, its behavior can be modeled 'as if' it were a homogeneous node of knowledge and preference – for example, a firm in the context of defining an alliance with other firms, or a functional unit in the context of defining a new product with other functions. Second, another important sense in which decision making can be qualified as 'organizational' is not related to the multiplicity of actors, but to whether an actor is deciding out of an organizational role or on a private basis (Barnard, 1938). Third, although earlier ODM research has been focused on processes going on within the institutional boundaries of organizations as entities (firms, public agencies, etc.), the main propositions and models are actually applicable to any ongoing cooperation, including interorganizational relations.

Hence, we shall adopt here a broad definition of ODM as both single actor and multiple actors, provided that decisions are taken in an organized context: ongoing relations among actors (not instantaneous transactions), but not necessarily internal to an entity, acting for some purpose of effectiveness (not just for leisure and pleasure). (In spite of its breadth, this definition leads to exclude from our analysis of ODM those 'phenomenological' traditions that have described all kinds of decision behaviors that may be observed in organization, without an interest in modeling their properties or conditions for effective or ineffective occurrence.)

As to the meaning of 'decision making,' the minimum common denominator of all notions can be found in the etymology of the term: 'de cedere' means cutting out, partitioning, discriminating, separating, and opting for some thing(s) rather than others. This activity may be performed in a deliberate and conscious way or not. In an organized context, deliberate and conscious action is of course particularly important, as effectiveness matters. Utility theory models coming from economics, as well as most models generated by the 'cognitive revolution' in interpreting human behavior are in fact of that type. Nevertheless, all deliberate decision-making processes are unavoidably embedded in other processes and factors that drive, constrain, and reduce the variety of possible actions that go beyond actor control and deliberation. On one side, those factors are embodied in the actors themselves, as 'taken for granted' and inherited background knowledge (Simon, 1990), or as 'normative' and 'affective' factors (Zey, 1992). On the other side, decision making is embedded in ecological processes, whereby it is the context/environment that in the end selects proper or viable actions, 'as if' actors' actions were random or blind variations. (To avoid confusion, it should be noticed that the term 'ecological rationality' has been used with various different meanings. In its strongest meaning, it has been used by organizational ecologists, in the sense that 'it is the environment that optimizes,' by selecting actions by means of selecting the subjects carrying them. In a second meaning, it has been contrasted with constructivist rationality (see Vernon Smith's Nobel Lecture) to refer to the emergence of 'patterned action without design' out of the combination of myriads of actions, in turn largely 'determined by cultural and biological inheritage.' Third, it has been taken to refer (e.g., by Gigerenzer and some related authors) to what in decision-making research (and in the present article as well) has always (and I think more properly) called 'contingent rationality': the deliberate choice by a subject, of a decision strategy deemed appropriate to (his model of) the environment/problem at hand (actually more a 'metaconstructivist' rather than ecological notion of rationality).) Actually, before the upsurge of cognitive sciences, decision behavior was predominantly interpreted in terms of instinct and affect or in terms of context-driven selection of actions.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.73076-5

Herbert Simon (1955) provided the most prominent foundations to the entire ODM field and put cognition center stage with respect to both 'ecological' rationality and to unconscious and emotional impulses. In his founding works, Simon, as well as some other important social scientists concerned with the foundations of human action (as Kelly and Bandura) criticized behaviorism and psychologism and invited to develop a variety of cognitive models of decision making, suspending a view of human behavior as driven by imperscrutable intuition and emotion. This invitation did not go unheard; actually it had a paramount influence on the evolution of the field. Simon kept a door open to the possibility that once the cognitive modeling of decision making would have been mature, eventually 'the pendulum would have swung again' toward an analysis of their relations with affective factors – something that in fact is an emerging trend nowadays (Gavetti et al., 2007; Hodgkinson and Starbuck, 2012). (Less fortunately, also the use of the notion of 'intuition,' as contrasted with analytic decision making, is reemerging in ODM literature. However, as Simon repeatedly noticed (e.g., 1989), distinguishing (no matter whether for opposing or blending) 'analytic' from 'intuitive' thinking is logically incorrect, because no one knows what intuition is; it is like distinguishing processes which have been analyzed from processes that simply have not been. Actually a core aim in Simon's research program was precisely to discover which logics, which types of analyses, methods, heuristics lay behind what we call intuition or even genius. Hence, here we do not make any use of the term intuition.) Anyhow, models of decision always imply a mix of constraint and freedom (Loasby, 1976): that very mix is what makes choice an interesting activity, with respect to being completely determined (if there is no choice, decision is impossible) or completely unconstrained (if everything works, decision is irrelevant).

The 'Logic' of ODM

The Rationality Divide

The history of thought on ODM did have a 'big bang,' with the concept of 'bounded rationality' (BR) (Simon, 1955). The theory was developed in contrast with utility theory, the dominant model of conscious, purposeful, effectiveness-oriented decision making available at the time, developed especially in economics, and applicable to the behavior of either individual actors or collective organized actors. Since then, most expositions of ODM models are 'anchored' to that model, in the sense of elaborating new models by relaxing some of assumptions of that approach, as to both knowledge and interest, considered to be very restrictive. Those assumptions are deemed to be narrow as they include knowledge of all the relevant alternatives and possible states of the world on a matter or problem, as well as the consequences of their combinations and their possible value (utility) for the decision maker (Simon, 1955). The economic model of rational ODM is still summarized in this way in most accounts (e.g., Hodgkinson and Starbuck, 2012) and 'therefore' considered to be practically 'inapplicable.' A minority of scholars have in turn criticized this characterization of 'value maximization' as a straw man, and pointed out that a complete knowledge assumption is different from a value maximizing strategy, which is nothing else than a set of procedures that can be applied with claim of efficiency *if* the problem at hand is 'closed' (Nutt, 1976), the alternatives in the relevant set are countable (Hatchuel, 2001), the task at hand is not too complex (Beach and Mitchell, 1978; Payne, 1982; Peters, 2003), and if knowledge on cause–effect relations as well as on preferences is available (Thompson and Tuden, 1959) or can be constructed in a valid and reliable way (Grandori, 1984). In those works, accordingly, the ODM models 'alternative' to value maximization are considered as alternative, *contingently effective decision strategies*, applicable in other circumstances, not as rival theories of ODM. Therefore, the adoption of alternative decision strategies is seen as metarational behavior rather than as a form of incapacity or of practically useful but inferior, or even biased thought (as it became in the 'heuristic and biases' behavioral decision theory). For one reason or another, anyway, most scholars agree on the point that, on most problems, actors (either individual or collective) cannot or even should not model problems so that utility maximizing calculations are applicable, either because it is too costly or cognitively unfeasible to do so, or because it would require to simplify problems to an extent at which they no longer represent reality well. In addition, economists themselves have highlighted that the existence and uniqueness of optimal solutions faces limitations and paradoxes in many multiple actor, multiple interest, interactive decision-making situations. The main alternative models, with a claim of being applicable and predictive under conditions of strong uncertainty and conflict of interests, are illustrated next.

The Classic Continuum of ODM Models

Simon outlined the most important of these models, the '*satisficing model*' of search and choice. The simplest basic version of that model states that actors will accept the first encountered alternative superior to a given aspiration level, truncating search at that point. If it is difficult to find acceptable alternatives, aspiration levels fall, and if it is easy, they rise. In that version, satisficing would describe primarily a decision behavior capable of generating 'good' solutions while reducing the costs of search.

Various other decision models, with claims of being able to manage even stronger conditions of uncertainty and conflict, have also been formulated in ODM research.

An '*incremental model*' has been identified in research on ODM especially in the context of public administration (Lindblom, 1959). A starting provocative empirical finding has been that the best predictor of a year's budget for a program or activity in local government is the budget of the previous year (Wildavsky, 1964). In an incremental process, the decision system should be able at least to discern where it wants to go: increase rather than reduce production capacity, improve levels of education, and increase well-being. However, it can generate action without making use of theories on the cause–effect relationships that regulate how the action system works and changes. Rather it employs a 'linear' choice rule – try 'incremental' solutions that differ marginally from those in use and learn afterward.

A *cybernetic model*, built in conceptual frames such as of control theory and stimulus/response behaviorism, relies even more heavily on *ex post* learning, and more precisely on learning by reinforcement (Steinbrunner, 1974). A cybernetic decision strategy implies only the following kinds of judgement: the capacity to recognize situations (e.g., a configuration of costs); the capacity to recognize performance gaps with respect to a standard (works/does not work; positive/negative); and possessing a repertory of possible actions that are applicable to eliminate the gap or respond to the situation, adjourned by a principle of reinforcement (repeat successful action, avoid previously failing actions). Processes that can be described and predicted fairly well as cybernetic processes range from some real-time unreflexive stimulus–response motivation processes to some innovation processes (e.g., the diffusion of codified technologies).

A *garbage can model* of ODM, elaborated in the early 1970s and enjoying a period of significant popularity afterward, can be seen as a limiting case, in which actions are tried at random, guided by chance encounters between actors, with an opening of attention at a certain time, and the emergence of choice occasions (Cohen et al., 1972). It is supposed to be relevant especially under ambiguity: Research using that model has typically studied institutions or processes with 'ambiguous' goals or highly unpredictable consequences (e.g., universities and cultural institutions). Although it has been seen as a provocative criticism of the means-ends 'determinism' of rationalist models of ODM, and as opposed to rational choice, the actual finding of the 'garbage can model' is that if knowledge and preferences are unclear, and alternatives tend to be 'undistinguishable,' then random choice (with eventual *ex post* learning) is the only (and arguably rational) option.

In sum, the main ODM models specified in the second part of the 1900s have been developed by relaxing and extending some of the conditions of uncertainty and conflict which characterized Simon's initial satisficing model, similarly to how the latter model was developed by relaxing and extending some conditions characterizing economic value maximizing models.

The general pattern envisaged and the implicit or explicit conjecture laying behind all these models is that the higher the level of uncertainty and conflict among interests becomes, the less 'rational' the sense of comprehensive and deductively ordered the logic of ODM becomes; the less investment in *ex ante* knowledge acquisition and the more reliance on *ex post* learning is made; and the less preferences are integrated and limited agreement is sought on action.

This orderly range of discrete behavioral alternatives on a 'continuum,' though, does not tell the whole story, nor makes justice to more recent developments in ODM research.

First of all, the decision procedures and heuristics that 'usually characterize' a decision pattern or model may actually be *combined* to generate hybrid decision behavior that better suits circumstances or captures the advantages of different decision modes simultaneously. Actually, it can be noticed that decision rules traditionally belonging to different models, being respectively focused on the different subprocesses of search, choice and learning, may well 'need each other' and be complementary rather than alternative (before applying any choice rule, a problem needs be defined and alternative generated through search and research; and any choice, even if taken according to a correct procedure, may result to be wrong upon test, hence learning is always worthwhile). In addition, it has been noticed early that *all* these traditional models, including both classic maximizing models and classic BR models, do not seem to encompass all feasible decision behavior or to specify the 'continuum' of decision strategies (if it is a continuum) completely. What is neglected is that in decision making, as in any knowledge-based processes, there are 'epistemic' issues, which perhaps are the most important issues, such as interpretation and mindful 'sense-making' (Weick, 1979), the reliability of information and of action based on it (Weick et al., 1999), and the validity of the knowledge generated and used in the process (Grandori, 2010). In one word, 'epistemic rationality' is of paramount importance in good judgment under uncertainty, but it has not been well represented and analyzed in the classic models of ODM.

More precisely and provocatively, traditional ODM research falls short of modeling those decision behaviors which respond to uncertainty not by avoiding it, but by investing in research and knowledge construction, and more precisely in reliable and valid knowledge generation, thereby leading to effective discovery and innovative decision behaviors (Grandori, 1984). At the time this observation was made, though, innovation was not so central as it is nowadays. In the next section, more recent research on effective ODM for innovation, which can fill this gap, is reviewed.

ODM for Innovation and Discovery

A fair amount of research is available on ODM in areas such as entrepreneurship, technological innovation, and strategic innovation. Studies on decision processes in the more innovative and knowledge-intensive parts of the economy show a rich array of decision procedures and heuristics that interestingly differ from those contemplated in the classic approaches so far considered. Rather than postulating a reduced content or a weaker form of thought in decision making as uncertainty increases, research on innovative ODM overall highlights that the opposite strategy – invest more effort and use stronger forms of thought – is conceptually and empirically possible, and even justified as a 'superior' strategy according to the canons of logics and epistemology, as a set of 'rational heuristics' for discovery. (See Grandori (2010, 2013), for a wider review and assessment of those heuristics, as well as for indications of the various studies from which they can be extracted, which cannot be quoted here for reasons of space.) For example, research on the entrepreneurial discovery of new products and services has consistently shown that effective logics include 'disciplined' and 'systematic search'; the reasoned formulation and controlled test of hypotheses; and processes of 'theoretical' and 'causal' modeling, rather than only of experiential learning. Research on the logic of technological innovation has highlighted how it can exploit the multifunctionality of resources and the multipurposedness of action, whereby logics of 'resources/alternatives in search of uses/problems to be solved,' rather than the classic reverse, can increase the rate of success in discovery and reduce downside risk in implementation. Studies on processes of strategic innovation are rich with instances of what Bandura called a 'modeling' approach to the discovering and learning of successful action, as opposed to

experiential direct or vicarious learning: constructing causal models of a situation using theory and relevant empirical evidence rather than 'experience,' and then 'test' them through action.

Considered together, these ODM processes can be considered as offering a further broad family of 'epistemic' models of ODM, complementing the two classic families of 'economic' and 'behavioral' models.

The 'Politics' of ODM

The Power/Efficiency Controversy

A different track of development of ODM studies has been concerned more with the problem of diverging interests and the relative 'weight' or power of actors holding them than on the problem of knowledge. A starting point has been a criticism of Simon's 'administrative man' for 'neglecting,' or not being particularly concerned with, the political and strategic dimensions (Pettigrew, 1973).

American ODM research on the politics of ODM has often contrasted organizational actors' power with organization system's efficiency, showing empirically that often the particularistic objectives and interests of subunits have more weight on the allocation of resources than the overall effectiveness and efficiency objectives held by the central agents of the system (Pfeffer and Salancik, 1974) and that 'subgoal pursuit' typically leads to 'fatter' organization (e.g., larger slack, larger organizational boundaries) (Williamson, 1964).

European studies have considered actors' power in a more positive light, casting the ODM problem as 'the integration of the many,' as contrasted with the 'one actor theorem.' (See Grandori (1995) for a review of the European tradition in ODM.) Research conducted in that perspective has been especially concerned with the strategic use of uncertainty and the determinants of the decision weight of organizational units and groups (Crozier and Friedberg, 1977; Hickson et al., 1971). It has been argued and found that the relative influence of organizational actors in ODM is a function of 'the control of critical uncertainties,' of the degree of substitutability, of the centrality in work and information flows, and of the perception and use of these *atouts* as bases of negotiation power. In that perspective, then, organizational power is a dependent rather than independent variable, and its allocation as a function of critical uncertainty may even be considered efficient, rather than an alternative to efficiency (Grandori, 1993).

A critical observation, on this way of 'extending' ODM models for accommodating conditions of different interests, is parallel to that raised toward the type of 'extension' of economic models of decision making for accommodating strong uncertainty provided by BR models. In the face of strong conflict, as in the face of strong uncertainty, and especially in the face of both, a loss of rationality and fairness is expected. An objection to this position is that this is not the sole possible behavior, nor it seems to be the best response that social and economic actors may be capable of. Also on the terrain of conflict resolution under uncertainty, a 'third' approach is possible and indeed followed both in theory and practice. Streams of studies highly relevant for ODM, combining the acknowledgment of both conflict and uncertainty, and a concern with efficiency and equity in conflict resolution do exist, although they are seldom included in standard reviews of ODM.

Conflict Resolution for Efficiency and Equity

Organizations are typically systems composed by parts. Actually one basic definition of the organization of a system is the mode in which it is partitioned and in which parts are related. Hence, it is more the rule than the exception that a system cannot be modeled properly as 'one single actor,' It might be so, for some classes of decisions (as clarified in the Introduction). But for most decisions, the 'locus' of knowledge and interests is more elementary than the entire organization; actually one basic raisons d'etre of organization is precisely to integrate and coordinate a constellation of interdependent nodes of knowledge and preference. Therefore, rather than asking whether power or efficiency are more important in actually shaping organizational structures and actions, in this perspective the relevant question is to devise structures and actions that are 'superior' for all the relevant actors having a claim to decide on a matter.

A core mechanism which may sustain this type of search is negotiation. There is plenty of evidence, in the negotiation literature, that many if not most organizational actions, and even organization structures themselves, are defined by negotiation. A negotiation perspective is quite different from a 'power perspective' as, while not neglecting the bargaining power of the actors, negotiation analysis provides tools for assessing solutions in terms of efficiency and fairness.

Negotiation is not the only mechanism for solving conflicts in an efficient and fair way though. Other coordination mechanisms are effective alternatives and/or complements to negotiation and negotiated orders in the governance of pluralistic systems and have also been studied in strands of organization studies connected or contiguous with ODM research: for example, voting and organizational democracy constitute another important alternative; alternatively, gaming through both unilateral strategies and coalition formation are possible and indeed likely and can be assessed in terms of Pareto efficiency and fairness and equilibrium of solutions. If these 'voting and gaming' conflict resolution mechanisms have to work effectively, though, problems need be structured, alternatives well defined, and payoffs clear; hence they are applicable to narrower conditions with respect to negotiation.

Hence, the models concerned with the 'politics of ODM' could be ordered on a sort of continuum, as the models concerned with the 'logic of ODM.' Again, the selection of a mode can be conceived in contingency terms, as a function of the clarity and differentiation of knowledge and interests. If at one extreme we locate systems for the aggregation of well-defined preferences over well-defined alternatives, as vote-based organizational democracies and gaming-based organizational poliarchies, at the other extreme we may find 'organized anarchies' (Cohen et al., 1972). In fact, the latter type of decision systems and processes has been identified and connected to conditions of extreme ambiguity, in which preferences and participants themselves are unclear/shifting; there is no predefined pattern or mechanism according to which to take decisions, and everyone is free to address any problem and coalesce with any other actor.

Although connected poliarchies, democracies, negotiated orders, and organized anarchies provide alternatives to markets and hierarchies for governing pluralistic and interdependent decision making in complex systems, those distributed decision-making systems also have costs and limits and differ in terms of the types of performance outcomes they are more likely to produce.

Economists have typically emphasized that the wider and more internally differentiated the set of actors holding decision rights, the better the representation/fairness of the decision system is, but the costlier decision processes are. On the other side, differentiated and integrated ODM, either through simple aggregation of preferences and judgments, or, and even more, through voice, discussion, and negotiation, is likely to produce more innovation than either a disconnected poliarchy or a completely connected and homogeneous community (Grandori, 2009).

The costs and difficulties of all these pluralistic governance decision systems can be shifted downward, though. One way is the institutionalization of framing norms and rules, of 'constitutional orders' which reduces the 'degrees of freedom,' and the variance in actors' preferences; that is, the embedding or blending of conscious, deliberate, ad hoc analysis and choice with the suspension of critical judgment in certain zones of action. Another way is to increase the capacity of information processing through information systems: A set of supports that in the current context of massive development of information and communication technologies (ICTs) are obviously gaining importance and radically enhancing the feasibility of distributed decision making.

Finally, as for decision strategies, recent contributions have highlighted that solutions may be improved and trade-offs simplified by *combining* coordination mechanisms, rather than considering them as mutually exclusive. In fact, in a design perspective on distributed ODM, there is an increasing awareness of the imperfections and paradoxes of any single mode and model and a combination of them recommended to sustain effective and innovative ODM (Grandori 2013).

Concluding Remarks

A Twofold Trend

It is common to recognize that the economic and social world is becoming increasingly complex, more uncertain, differentiated, and conflict laden. The evolution of ODM models in fact is marked by attempts to address increasingly complex conditions. However, this trend has been twofold: Two different types of response and direction of study can be identified in the ODM models for a complex world.

On one side, there are models and studies driven by the hypothesis that in the face of an increasing complexity of the world, thought becomes weaker and rationality more and more limited, with respect to both problem solving and conflict resolution.

On the other side, there are models and studies building on the hypothesis that in the face of the increasing complexity of the world, actors *can* stretch and strengthen their minds, invest in research rather than reduce search, and try to solve conflicts by devising fair higher-order rules of the game and constitutions rather than indulge in power games.

These two trends may well reflect a polarization of ODM system in reality. The first type of reaction is likely to be more common, to describe well average behavior, but to 'leave resource on the table.' The second type of reaction is likely to be less frequent but 'superior,' likely to be found in 'outliers' more than in mainstream practice, but inspired to the 'best patterns of thought and action' that are logically and practically possible. As an agenda for future research, the second perspective may deserve more attention, not only because the majority of mainstream ODM can be located in the first approach, but also for its higher potential for improving ODM under complexity.

Implications for Structures

ODM is influenced by organizational architectures, and vice versa structures are influenced by ODM processes and approaches. Information processing-based organization theory stated a wide set of propositions on how to design organization structures so as to set 'decision premises' stimulating more optimizing and computational decision processes in units dealing with structured tasks and devoted to the exploitation of existing resources, leaving space for more heuristic and experiential approaches in unstructured task environments and exploration-oriented parts of the organization.

The enrichments that occurred in decision models for knowledge-intensive and innovative decision making highlighted that in those conditions there are further implications for structures. Organizational systems should become, almost by definition, less 'decomposable' if problems are not known enough for being decomposed and new knowledge is to be generated in ODM processes. Hence, somewhat contrary to some current organizational fashions, effective structures for the growth of knowledge should be expected to become not only less hierarchical, but also more connected, that is, less 'loosely coupled' and less 'modularized' (in fact, hierarchy is quite modular a system). The general principle that, in managing uncertainty and innovation, both differentiation and integration are required, seems to remain valid; however, the forms of specialization and coordination that are likely to be most innovative are expanded by the examined recent trends in ODM. The classic notion was that some units should be flexible and exploration oriented and some structured and devoted to exploitation. The emerging model is more networked: If the growth of knowledge is central, the 'parts' or units should be characterized by differentiated knowledge that should be all integrated to contribute to organizational learning. As illustrated in the decision logic section, heuristics such as 'resources in search of uses' and multipurposedness imply that the very search for better exploitation of existing resources implies exploring new uses, activities, and services. Hence, in terms of future research, some of the currently popular distinctions in ODM, in particular that between 'exploration' and 'exploitation,' may deserve some revision in the light of the logics of ODM for innovation and discovery specified in recent research.

More horizontal, paritarian, pluralistic, and representative organization forms should also be favored by the multiplication of the relevant actors and constituencies, as

illustrated in the politics of decision-making section. To put the study of pluralistic governance arrangements high on research agendas seems to be overdue in economic and management sciences, still seeing governance as limited to command-based, incentive-driven, or conflict-free communitarian alternatives. The development of new information and communication technologies should provide extensive and yet far from fully exploited support to forms of ODM that are both pluralistic and connected.

Abstract

Organizational ecology refers to a sociologically oriented research program on organizations. It involves the empirical study of populations of organizations and a theoretical emphasis on processes of selective replacement of relatively inert organizations. Much organizational ecology research uses common methodological presumptions and practices, including the analysis of entry, exit, and growth hazard rates in large historical populations from their dates of origin. Development and testing of ecological theory has taken place within cumulative theory fragments, such as niche width, density dependence, and resource partitioning. Each fragment addresses focused research problems in a coherent way using middle-range theory. Combining the theory fragments remains an unrealized goal, but one which has spurred a great amount of theory and research on how institutionalized social categories shape organizations and guide organizational action.

Organizational ecology (OE) is a major theoretical perspective that attempts to explain organizational diversity, famously framed by the orienting question of Hannan and Freeman (1977), why are there so many different kinds of organizations? OE uses a selection model of organizational evolution to explain organizational diversity in a population. In the imagery of this model, organizational change over time occurs through the selective replacement of some kinds of organizations in the population with other kinds as environmental circumstances change. In selection models, at any point in time the environment operates as a screen, letting ill-fitted organizations fall through or fail and catching or supporting better-fitted organizations. Selection models assume individual organizations face constraints that limit their abilities to make major transformations, which meet the changing demands of the environment (Hannan and Freeman, 1984). Accordingly, research in OE focuses on the vital rates of populations – rates of founding and mortality in particular, although growth and transformation remain of interest. Selection-driven evolution is sometimes mistakenly thought to lead to a narrowing of organizational diversity, a winnowing. Although winnowing may be more likely when constraints such as regulation limit new entry, various selection processes can drive population diversity up or down (Carroll et al., 2012).

One foundational pillar of the OE research program examines the demography of organizational populations. It finds that organizational mortality processes depend upon the age and size of the organization, as well as on characteristics of populations and environments. Moreover, research confirms an imprinting process, meaning that environmental conditions at certain early phases in an organization's development exert long-term consequences. In particular, organizations subject to intense competition show elevated mortality hazards at all ages.

OE theory invokes a central assumption of structural inertia, the tendency for organizations to respond slowly relative to the speed of environmental change. A core argument holds that inertia derives from the very characteristics that make organizations favored kinds of actors in modern society: reliability and (formal) accountability. It follows logically that change in an organization's core features disrupts activities and increases the hazard of mortality, at least in the short-run, a prediction supported empirically (Barnett and Carroll, 1995).

Within OE, the niche concept organizes theoretical ideas relating environmental variations and competition to population vital rates. The niche specifies the resource space within which a population (or even an individual organization) exists. Much empirical work in OE examines the niches of organizational populations along dimensions of social, political, and economic environments, a tradition dating back to the human ecology of Hawley (1968). Recent research conceptualizes niches in terms of identities within institutionalized categories, an approach that has proven very insightful (Ruef, 2000; McKendrick et al., 2003).

Development and testing of ecological theory has taken place within cumulative theory fragments. Each fragment addresses focused research problems in a coherent way using middle-range theory (Merton, 1968). Within basic demography, fertile fragments include aging, inertia, and niche width. Major fragments dealing with population dynamics include density dependence and resource partitioning.

The theory of density-dependent organizational evolution integrates ecological and institutional processes. It posits that growth in the number of organizations in a population (density) drives processes of social legitimation and competition that, in turn, shape the vital rates. This argument implies certain nonmonotonic relationships between density and rates of founding and mortality.

Resource-partitioning theory concerns the relationship between increasing market concentration and increasing proliferation of specialists in mature industries. The key implication of this theory concerns the effects of concentration on the viability of specialist organizations (those that seek to exploit a narrow range of resources).

The Basic Demography of Organizations

With its concentration on the vital rates of founding and mortality, OE has a strong demographic character. Key

structuring processes are specified at the population level. Mortality histories can readily be associated with individual organizations, but histories of foundings cannot because the absence of foundings in some period or place must be considered. Populations must have unit character to serve as useful objects of analysis (Hawley, 1968). Researchers generally regard populations as spatial–temporal instantiations of organizational forms, templates for organizing. Several conceptual approaches to form have guided these efforts: common resource dependence, structural equivalence in network position, and more recently identities coded in cultural rules, especially institutionalized categories.

Constructing organizational demography and ecology requires attention to how organizations differ from organisms. In particular, organizations experience more varied 'birth' and 'death' events, typically lack clear 'parents,' consist of multilayered, partly decomposable structures, and can transform themselves into very different kinds of entities. Methodological issues in OE often involve dealing with these complexities (Carroll and Hannan, 2000; Phillips, 2005).

The prototypical OE research design examines the full histories of organizational populations, because experience shows that early events can exert lasting consequences for population dynamics. The design gathers life-history data on all organizations in the population(s), including the large and famous as well as the small and insignificant; such inclusiveness is crucial for avoiding problems of selectivity bias. The design records detailed information about type of entry (new founding, entry from another industry, merger, etc.) and exit (disbanding, acquisition, transformation, etc.). Finally, it uses event-history methods to estimate the effects on vital rates of characteristics of organization, population, and environment. Used earliest by OE analysts, this focused population design diffused widely to other kinds of organizational research; and now seems primed to affect the study of products (Khessina and Carroll, 2008; Carroll et al., 2010).

The prototypical OE design typically uncovers many more organizations operating in well-studied industries than is usually assumed. Careful archival searches usually find information on hundreds of organizations that get overlooked in published counts, some because of their small size, and some because of their ephemerality. Analysts using traditional approaches counting only bigger and more stable organizations defend the exclusion of these entities based on their apparent minimal impact on major economic and social outcomes. However, ecologists point out that minimal impact at any given point does not preclude subsequent impact, or potential impact, an insight of evolutionary approaches. Classic examples of companies that might be excluded by such rules would include Microsoft, Apple, and Google at the time of their origins, leading the analyst to either include them retrospectively based on later performance (creating selection bias) or including them only when they reach a certain size (creating an unnatural 'founding' date).

An unexpected insight generated by the prototypical OE design was that the foundational periods of industrial populations often show activity typically seen in social movements, apparently noncommercial pursuits. Carroll and Hannan (2000: p. 231) made the general observation that: "To say that the origin periods of industries resemble social movements means that (1) they represent challenges to existing companies and industries, and (2) they are populated with individuals and organizations devoted to causes, lifestyles, and visions of a better future for all (rather than with profit-maximizing entrepreneurs engaged in competitive battles based primarily on self-interest)." Other insights from social movement theory have subsequently been added to OE analysis (Wade et al., 1998; Rao et al., 2003).

The OE design also reveals that organizational life expectancies are generally an order of magnitude smaller than for humans, prompting great attention to organizational aging. Stinchcombe (1965) observed that organizations (and organizational populations) experience a liability of newness. Efficient organization requires trust among members, which takes time to build. Creating roles and routines, learning about the environment, and developing relationships with other organizations also take time. Once established, these patterns of relationships enhance survival chances. Much early research found this pattern. Some later research found a variation, a liability of adolescence: the hazard rises during the early lifespan – while initial stocks of endowments get exhausted – before declining. Recent research, using designs that measure (age-varying) organizational size, has produced (mixed) evidence in favor of positive age dependence (Carroll and Hannan, 2000).

Two interpretations for this pattern have been proposed (Barron et al., 1994; Sørensen and Stuart, 2000). If inertial forces are strong, then the possibilities of adapting to changing environments are limited and older cohorts of organizations have lower fitness – there is a liability of obsolescence. Alternatively, the accumulation of rules and routines impedes adjustment to environmental change – the liability is one of senescence.

Subsequent research sought to clarify the conditions under which the various patterns rise. Hannan (1998) proposed a partial integration using first-order logic. The next step required use of nonmonotonic logic, which allows premises to be overridden by more specific ones so that the conclusions of an argument can change as more knowledge about specifics becomes available (Hannan et al., 2007). In recent work, Le Mens et al. (2011) revised the theory in terms of the stock of organizational capital and show that the various patterns of age dependence can be integrated using weaker assumptions.

Inertia and Selection

Stinchcombe's (1965) insight that new organizations get imprinted by their environments provided inspiration for organizational ecologists. According to Stinchcombe, new organizations get tested against assumptions that are taken for granted but change over time. Hence, the characteristics of organizations which pass such tests and emerge will reflect the social structure of the time. Imprinting requires both a mapping of environmental conditions onto the organization and inertia in the imprinted characteristics. Absent the second condition, later adjustments will erode the association between founding conditions and those features.

OE analysts built on this image of inertia (relative to the speed of environmental change). Hannan and Freeman (1984)

claimed inertia prevails as an inadvertent by-product of a selection process favoring the properties of reliability (low variance in the quality of performance) and accountability (the ability to construct rational accounts for actions). Achieving these properties depends on structures being reproduced faithfully over time. Yet, high reproducibility means that structures resist transformation. Therefore, this selection process inadvertently favors corporate actors with strong inertial tendencies.

Fundamental change presumably diminishes reliability and accountability. Old learning loses value, and new processes must be learned. Vestiges of the old system conflict with the new emerging system and disrupt activities and operations. Thus, even if the intended change has long-term benefits (the new form might be better aligned with environments and internal processes), the change process might increase mortality hazards in the short-run. If so, then reorganization-prone organizations are less likely to be present in future populations.

Ample research examines the implications of this argument. Most well-designed studies reveal that changing core structures does indeed increase the hazard of mortality in the short-run, often substantially (Carroll and Hannan, 2000). Moreover, the magnitude of this effect increases with organizational age.

A different way of viewing imprinting yielded one of OE's most robust empirical findings: density delay (Carroll and Hannan, 1989). Organizations subject to intense competition at founding (as evidenced by a high density of organizations in the population – see below) have elevated mortality hazards at all ages. In other words, density at founding has a (partially) delayed effect on mortality processes. This relationship has been interpreted as reflecting enduring effects either of building structures under scarcity or of initial organizational positioning at the margins of resource distributions.

More recently, theorists suggest that identity enforcement processes might generate inertial mechanisms as well as punishments for fundamental changes (those that violate codes – see Zuckerman, 1999; Hannan et al., 2007; Hsu et al., 2009).

Organizational Niches and Institutionalized Categories

Within OE theory, the niche concept organizes ideas for relating environmental variations and competition to organizational demography and population dynamics. An organization's or a population's fundamental niche consists of the ranges of environmental parameters for which its growth rate (fitness) is nonnegative in the absence of competition. Much empirical work in OE examines the niches of organizations and populations in terms of dimensions of social, political, and economic environments (e.g., Dobrev, 1999; Boone et al., 2004; Goldstein and Haveman, 2013). Even when such issues do not stand in the forefront theoretically, ecologists routinely control statistically for the effects of such dimensions in examining dynamic processes.

Recent efforts to rebuild the foundations of the OE theory depict organizational forms as based on culturally coded and enforced identities (Hannan et al., 2007). These identities operate within institutionalized social categories, agreed upon classification systems that shape the organizational world with labels and associated schemata. For instance, 'private liberal arts college' represents a type of higher educational organization which likely contains many specific features about its personnel, employee contracts, technology, funding base, impact, and the like. Organizations may be more or less members of specific categories, defining their 'grades of membership' in a category, and organizational may span across multiple categories, thereby increasing their niche width in the space of categories. Boundaries between categories may be strongly or weakly enforced by institutional gatekeepers and others. And, categories vary in their apparent distinctiveness based on category permeability and organizational distributions; ecologists describe these variations as category 'contrast' (Negro et al., 2010; Kovaçs and Hannan, 2010).

Niche theory has been central to research on competition (Hannan and Freeman, 1977, 1989; McPherson, 1983). Populations compete if the presence of each reduces the spaces in which the others can sustain themselves (their realized niches). By this reasoning, populations compete if and only if their fundamental niches intersect. The assumed equivalence of niche overlap and competition plays a crucial role in allowing organizational ecologists to relate empirical observations on realized niches to models of population dynamics.

Niche width concerns the variance of resource utilization. Does evolution favor populations of Jacks-of-all-trades and masters of none (generalists) or specialists at a few tasks? Ecologists call this the Principle of Allocation (POA) problem. Research shows that the organizational world tends toward segmentation into specialist populations (each highly isomorphic) when relevant environmental variations are uncertain, large in magnitude, and long in duration (Hannan and Freeman, 1989; Péli, 1997).

Recent research examines the POA problem in the context of form identities and social categories. This research asks, does category spanning lead to deleterious consequences for organizations? Findings to date suggest strongly that when an organization's niche width crosses category boundaries, the organization will pay a price in terms of recognition and valuation (Hsu, 2006; Hannan et al., 2007; Negro et al., 2010; Pontikes, 2012). The penalty seems to be more severe when the categories involved are defined in opposition to each other, for example, mass producer and artisanal craft producer.

Density Dependence

The theory of density-dependent organizational evolution integrates ecological and institutional processes. It posits that growth in the number of organizations in a population (density) drives processes of social legitimation and competition that, in turn, shape the vital rates (Hannan and Carroll, 1992). An organizational form gains (constitutive) legitimation when it becomes taken for granted (Meyer and Rowan, 1977). New organizational forms generally lack such legitimation, which makes organizing difficult. If the form gets promulgated, legitimation increases. Initially, when there are few organizations in a population and the form lacks legitimacy, the returns to legitimation of adding another organization are great. However, when the population

contains many organizations, constitutive legitimation increases little – if at all – as density rises further. In other words, a population's legitimation increases with density at a decreasing rate and approaches a ceiling.

Competition refers to the consequences of efforts by multiple agents to acquire the same limited resources. Density-dependence theorists focus on diffuse competition because it has a clear relationship with density as the intensity of diffuse competition within an organizational population rises as a function of the number of potential bilateral competitors. As density increases linearly, the number of possible competitive relations increases geometrically. Thus diffuse competition rises with density at an increasing rate. The theory posits that founding rates are directly proportional to legitimation and inversely proportional to the intensity of diffuse competition and that these relationships are inverted for mortality hazards.

This theory (formalized appropriately) yields two theorems. First, as density increases, founding rates initially rise, reach a peak, and then decline. Second, the relationship for mortality is the mirror image. These theorems, expressed in parametric forms, can be falsified empirically. They have been tested for diverse populations, including automobile manufacturers in Europe and the United States, brewers in Germany and the United States, banks in Denmark, Japan, Singapore, and the United States, and American labor unions, life insurers, newspapers, and social movements of women and ethnic groups. These studies have supported the theory in most cases (full citations can be found in Carroll and Hannan, 2000).

In recent formulations, density dependence plays a role in the cultural coding process of forms. Ecologists use this approach to weight density using grades of membership (Kuilman and Li, 2009; Boone et al., 2011).

Resource Partitioning

Resource-partitioning theory addresses market segmentation; it concerns the relationship between increasing market concentration and increasing proliferation of specialists in mature industries (Carroll, 1985). The theoretical imagery involves crowding in a heterogeneous market. Organizations initially target resource segments. Specialists choose narrow, homogeneous targets; generalists choose broad, heterogeneous ones.

The theory assumes an advantage of scale (in production, marketing, or distribution). Because organizations targeting narrow segments cannot grow very large, they have higher (per unit) costs. Organizations with scale advantages expand product offerings to broaden their appeal without losing established domains. Small organizations then face formidable invaders, and many fail. Competition is most intense in resource-dense centers, resulting in dominance by large generalists. Failures of smaller generalists cause some resources to become free. Because larger generalists can best secure these resources, the surviving generalists become larger and more general. However, generalists can rarely secure all of the newly freed resources. As the struggle among generalists proceeds to its monopoly equilibrium, the surviving generalists grow and broaden, but the set of resources they hold collectively actually declines. In other words, more resources become available for specialists as the market concentrates and their viability increases as well: specialist founding rates rise and mortality rates fall. Accordingly, the specialist advantage in concentrated markets comes as a consequence of strategic positioning by generalists in a market conceived of spatially (Péli and Nooteboom, 1999).

Subsequent formulations of the theory highlight the market attractions of specialist identities, clarifying certain issues in resource partitioning. Specialization based on claims of authentic identity (as in the case of the rise of specialist producers of microbrewed beer in the United States and 'real ale' in the United Kingdom) can prevent large generalists from gaining complete control of concentrated markets; this development makes it very hard, if not impossible, for generalists to compete, especially within certain categories (Carroll and Swaminathan, 2000; Koçak and Özcan, 2013). Generalizations of this insight have focused broadly on the appeal of products, services, and performances perceived to be authentic, because of aspects of the producer's identity (Carroll and Wheaton, 2009; Phillips, 2013; McKendrick and Hannan, 2013). Empirical support for the theory has been found in a variety of contexts including airlines, automakers, commercial and investment, brewers, whiskey distillers, microprocessor manufacturers, newspaper publishers, telephone companies, television broadcasters, and wineries (full citations can be found in Carroll and Hannan, 2000).

Emerging Trends

Current research seeks to extend many of these and other OE theory fragments, to connect to other social science research programs and to expand the range of applications to other phenomena.

As for extensions, the most active fragment by far is that concerning identities and categories. Work proceeds on fundamental issues such as how categories emerge, evolve, and impact (Negro et al., 2010b). It concerns organizations but also labels, boundaries, regulators, and other gatekeepers (Negro et al., 2010a; Hsu et al., 2012). The theory invoked in this program relies heavily on cognitive psychology and cultural sociology (Hannan, 2010; Negro and Leung, 2012).

OE analysts also keep integrating ideas about social networks into the analysis. Cattani et al. (2008) demonstrated how density-dependent legitimation grows hand in hand with development of the interorganizational network. Intriguing recent research on the relational structure of schemas within an audience shows promise for advancing understanding of audience dynamics (Goldberg, 2011; Koçak et al., in press).

Organizational status has been shown to affect organizational life chances, with the impact increasing with the uncertainty in evaluations of quality (Podolny et al., 1996). Kovacs and Sharkey (2014) show that status shocks sometimes produce unexpected audience dynamics. Social movement research relies increasingly on OE as a guide to modeling dynamics (Minkoff, 1997; Soule and King, 2008).

The empirical scope of OE continues to expand. Current research expands the diversity of organizational populations studied. In addition to those already mentioned, these include:

accountancies, bicycle manufacturers, computer manufacturers, disk-drive producers, footwear manufacturers, orchestras, hotels, law firms, magazine publishers, music recording firms, paper manufacturers, restaurants, sex shops, Islamic banks, and software producers. A major thrust of current work is on connections among the organizations (including flows of personnel among them). These studies highlight again the value of social network analysis for understanding the ecology of organizations.

Other important social and economic phenomena are also being brought into the picture. Studies of careers find that organizational demography induces considerable job mobility (Haveman and Cohen, 1994); at the same time, careers of managers shape strategies and thereby influence life events for organizations (Sørensen, 1999). The density and diversity of organizational forms in a community also apparently affect social and legal change (Koçak and Carroll, 2008; Boone et al., 2011; Negro et al., 2013) as well as the degree of civic engagement (Sampson et al., 2005), fulfilling the promise of Hannan and Freeman's (1977) orienting question about organizational populations.

Abstract

This article presents the emergence and evolution of an organization as a response to the demands faced by the newly created firm, shaped by a process of problem solving in response to change emerging both from the environment and from the firm itself. Successful firms are those that successfully adapt as demands evolve, in this case, specifically with respect to their organization. Such adaptation requires flexibility and diversity within the firm, attributes that must be shaped by the firm's managers.

Introduction

The main focus of this article is the creation and development of organization within new and young firms. In this article, organizations are viewed as more or less enduring groups of people in a collective with a common identity, engaged in some common activity that is structured through a division of labor (differentiation) and distribution of authority. Self-sustaining organizations can be viewed as input–output systems, obtaining resources from their ecosystem and transforming them into outputs that bring in the returns that sustain the organization. A commercial organization must appropriate and retain some of the value it generates through market transactions (revenue) if it is to continue (Davis, 1973; Casson, 1982). Not-for-profit organizations that rely on donors or public revenues also must generate value of some kind if external resource providers are to continue supporting them. Private sector firms, the basic units of a market economy (Edquist, 2005), are the focus of this article, with special reference to new firms, which widely are acknowledged to contribute to economic growth and industrial revitalization.

Despite increasing media and academic attention to organizations that are new entrants to industries, there are still many gaps in our understanding of how new organizations emerge and develop. This can be attributed in part to the fragmented analysis to which this topic has been subjected and partly to misapprehensions as to what can be explained. Penrose (1959) showed that the specific determinants and behavior of a particular unit, such as a firm, is inherently unpredictable, but nevertheless, we can aim to gain a better understanding of *processes* of development.

Building on the work of Penrose (1995), we focus on the processes of change in new firms (Garnsey, 1998; Brush et al., 2001). Applying the ideas of Penrose to the development of new firms shows how emergence is driven by both internal and external dynamics. We first look at new firm formation and value creation, from the perspective of firm growth and organizational evolution. We then examine firm fitness in relation to its business environment, considering both the firm's ability to influence its environment and the firm's evolution to fit its ecosystem. We then discuss dominant approaches to the study of new firm formation. We conclude with recommendations for further study and policy.

New Firm Formation and Value Creation

For a firm to survive in a market economy, opportunities must be detected and input resources obtained to produce offerings that can be exchanged for income over and above the cost of production (Druilhe and Garnsey, 2006). Thus, the firm must create value for customers equal or superior to market alternatives and capture enough value to keep the firm in business, Opportunity recognition, the building of a productive base and creating and sustaining returns, will be discussed in the following sections along with the organizational evolution that follows each step.

Opportunity Recognition

Perception of an opportunity to create value, either one that currently exists or could be created, is often what triggers the process of new firm formation by the founder or entrepreneur (Penrose, 1959). Firms are sometimes founded, however, before the business idea has fully taken form, as might be the case if a firm is founded to exploit a new technology without a clear choice of application. The availability of a new resource may raise awareness of an opportunity; for example, advances in genetics drew the attention of microbiologists to new opportunities in pharmaceuticals. The perception of a new market need may trigger awareness of an opportunity; for example, the need for reliable energy in developing countries is increasingly inspiring technologists and entre-preneurs to find low-cost energy solutions. Once organi-zations start to develop, that opportunity detection process is unlikely to be the preserve of a single individual, and the extent to which the firm is able to develop effective learning processes becomes important (Lumpkin and Lichenstein, 2005).

Early Organizational Development

The early development of the firm involves both maturation and growth. Development refers to a process of maturation involving changes in structure and activity, while growth in a firm refers to an expansion in size or other indicators. Emergence of the firm may be preceded by a period of preparation; as opportunity scanning, consultation, and discussion often take place before start-up, the date marking the formal

 http://dx.doi.org/10.1016/B978-0-08-097086-8.73099-6

founding of the firm is to some extent arbitrary. If this process takes place, the maturity and market readiness of the business concept on start-up is variable. Serial entrepreneurs or those spinning their firm out of an existing organization (such as a large firm or university lab) may have developed and even tried out a business concept in a previous organization; alternatively the initiative may be pioneering. Some firms are started by first-time entrepreneurs or with technology still in need of further development; for example science-based university spinouts. Such firms may grow significantly in terms of resource endowment and employees while still being far from market, as occurs in the case of science-based firms in which the technology has a long gestation period, as in biopharm and new materials.

The development of the firm from original concept to operational entity involves cumulative problem solving; the original ideas for the business are modified frequently, either because of resource availability or because the entrepreneurs' assessment of the opportunity shifts. In contrast to this experimental mode, the corporate strategic planning that occurs in established firms assumes much greater consistency of direction as required for hierarchical control and accountability.

Preliminary scanning for business opportunities gives way to management tasks as the new firm matures. But this does not imply that problems are solved once and for all as 'stages of growth' perspectives imply. Entrepreneurs frequently revert to opportunity scanning when their goals come into question or if they start another line of business. Scanning opportunities for new product introduction is a continuous process when product life cycles are short.

The opportunities open to the new firm and how fast it is able to grow initially depends on resource endowments the founders bring to the start-up. When founders bring unequal contributions to the ventures' initial resource endowment, this should be reflected in the founders' agreement that records the new firm's ownership structure at the time of incorporation. Among the benefits of founding a company is that company law can be used to define ownership and avoid some of the complications of multiple ownership. For example, lack of clarity over intellectual property (IP) and other ownership issues can result in conflict later on. Limited liability and company law offer further benefits to a firm registered as a company, beyond those available to an unincorporated form of organization.

Since it takes time to produce outputs that generate revenues, a critical initial issue is how to cover the costs of start-up. For entrepreneurs, convincing funders of the prospects for their venture is the key to openings beyond their own immediate means. They are more likely to attract investors on terms acceptable to them if they can develop and add value to their own resources. A working prototype is more valuable than a design and a customer base makes a firm more valuable still. The ability to attract finance depends on the entrepreneur's ability to 'create confidence' in investors (Penrose, 1995: p. 38). If confidence is lost, investors can withdraw support or exert other sanctions. Investors with a large stake in a venture sit on the new firm's board of directors. An entrepreneurial chief executive can be replaced by a dissatisfied board. Entrepreneurs who want to retain autonomy may choose to make do without recourse to external investment, at the risk of having too few resources to realize extensive opportunities.

Building a Productive Base

A key challenge is to build a productive base from which to pursue opportunities (Garnsey et al., 2006). This productive base is made up of all resources, including human, financial, physical, technological, and organizational resources, that are required to seize the identified opportunity (Clarysee et al., 2005). With regard to human capital, entrepreneurs have to find partners, assistants, champions, and other potential resource providers and convince them that they too can benefit from the proposed business experiment (Lubik et al., 2011). Many studies show that prospects are better for ventures founded by a team of entrepreneurs (Storey, 1994; Reynolds and White, 1997). Depending on the sector and business model of the firm, more or less financial capital must be raised. Physical and technological resources can be accessed through a number of often-creative arrangements (Garnsey et al., 2007). The resources required will differ according to the activity undertaken; for example, firms that chose to manufacture a complete product are likely to require a much larger resource base, in terms of financial and physical resources, than a firm competing in the market for technology (licensing).

The revenue-generating activities a firm plans to undertake, such as licensing, service, manufacturing, or franchising, have implications for both requisite investment and competition. The production of new IP (as opposed to IP inherited or bought from the new firm's initial endowment) requires a distinctive base for productive activity, as does software production (Arora et al., 2001). Scientific research often requires a laboratory base in a research environment, which is very costly to duplicate in a new firm. For this reason, young technology firms are likely to engage in partnership arrangements. But entrepreneurs' specialist skills can constitute a large part of the productive base if they use their knowledge base for consulting, which allows them to continue the development of their core technology while generating early revenue streams. At the other extreme, if the productive base is highly capital intensive (i.e., requires significant external finance and investment in physical assets), this constitutes a barrier to entry for most entrepreneurs. Activities that have low barriers to entry, such as catering, are inevitably subject to greater competition. To address common problems, some start-ups replicate management procedures used elsewhere. For example, franchising arrangements provide detailed specifications for operational procedures. Franchising arrangements guide the creation of a productive base in a new unit and accelerate start-up through imitation, but they prevent further innovation.

Because many organizations are concerned with using knowledge to solve problems for producers and users, a productive base that relies more on knowledge rather than physical output is increasingly common and distinctive (Teece, 1998). Knowledge cannot remain exclusive once it has been shared, and hence there is a need to find ways to create IP that can be protected from competition and bring in license fees and royalties through patents and copyright. It is

unusual for licensing revenues to be sufficient to sustain a company, except with valuable new medical entities or well-protected generic technologies. Protection usually is afforded by extensive patenting portfolios, but patents are difficult for a new firm to defend. Corporate partners licensing the technology from a new firm will have an interest in protecting its IP (to prevent competitors from obtaining it illegally), deterring potential patent infringers, as was the case for the chip design company ARM.

Organizing Productive Activity

In a firm that is set up anew, with no precedents to follow, the firm's productive activity involves a division of labor and methods of coordination that start out fluid and experimental (Utterback, 1994). As experience is accumulated, a problem-solving repertoire develops and ways of carrying out tasks and requirements are embodied in procedure (Lumpkin and Lichenstein, 2005). Roles are assigned and rules are adopted to save time and improve coordination (Mintzberg, 1979: p. 2). By drawing on previous learning, the emergence of routines can improve the organization of production and revenue generation. Over time, routines affect outlook as well as procedure. Solutions that have been found to work come to be taken for granted and part of the unconscious assumptions of the organization. Tacit knowledge is conveyed to new members as the way to do things. Underlying assumptions about how things should be done make up the emerging culture of the firm, which is influenced by the outlook and preconceptions of the founding entrepreneurs.

At first, tasks are shared but as soon as a division of labor sets in, specialist functions emerge: finance, production, sales, marketing, and human resources. In this way, the firm begins to develop competence, which is the product of problem-solving activities. Competences enable the firm to respond to changing opportunities and threats. The new firm develops problem-solving skills and embeds these in procedures and routines. Routines can be viewed as "patterns of interactions that represent successful solutions to particular problems" (Teece et al., 1997) and become regular features of the organization's way of doing things. As the firm grows more complex, standardization of procedures is needed so that decision making can deal mainly with exceptions and the need for supervision can be reduced (Cyert and March, 1963). Official standard procedures are available for purchase and can help firms learn from practices used elsewhere.

Creating and Sustaining Returns

Problems of coordination and direction become more acute as the firm grows more complex and may require skills beyond those of the founders. Thus, the rate of return can be improved by speeding up throughput in more rapid production cycles, resulting in shorter lead times from input to invoice. But even if professional managers improve efficiency, further expansion is by no means ensured. The original offering of a service, product, or product range will have to be updated or extended. Many firms are unable to generate or mobilize sufficient additional resources to support the growth they need to make them less vulnerable (Garnsey and Heffernan, 2005). Sales growth is needed to achieve the minimum efficient scale (MES) of operations in an activity or in cases in which only a higher level of market share can secure the firm against competition. To achieve MES, the firm requires additional resources and must retain talent through opportunities for promotion. This requires development capital, which is never easy to obtain from external sources. Retained earnings provide the most autonomous source of investment capital but are unlikely to be sufficient for new companies with few reserves. Servicing the interest charges on bank loans raises costs. These challenges make it difficult for young firms to show an increase in profits even where their output and revenues are increasing.

Whether or not a primary aim of the entrepreneurs is profit, opportunity realization depends on returns that cover costs and provide reserves to see the firm through contingencies that endanger cash flow. The need to be profitable was brought home after the dot.com crash during which investors lost patience with ventures burning through initial investment without advancing toward profitability. Failure to show profits can result in a vicious cycle of investor and customer withdrawal, outcomes that distorted accounting practices attempt to conceal but instead may precipitate.

Not all new firms achieve the competitive advantage or secure a rent-generating position that enables them to accumulate resources in a growing product and asset base (Tidd et al., 1998). The advantage of the minority who do so is reinforced through reinvestment of retained earnings. New opportunities may be identified – positively affected by the increased knowledge base of the firm. This resource accumulation process provides necessary reserves for dealing with the potential resource shortfalls (Cyert and March, 1963). Organizational slack, the amount of resources the firm has in excess of the minimum required to remain operational, provides a buffer against external shocks and offers the means to explore new opportunities without endangering the current resource-generation process.

The firm itself becomes a useful asset once it has a market value as an entity (Lubik et al., 2012). If the firm initially was funded with venture capital (this applies to only a small minority of start-ups), their investors may insist on an early exit route. Realizing the value embodied in the firm is a challenge, as the value is only made manifest when on exit (via a buy out, a takeover, or bankruptcy) or if the firm launches on the stock market in an initial public offering. The advantage of going public is that the firms' shares become a liquid asset that can be bought and sold on the market. In return for funding, however, the founder managers may have to cede control of the firm to a board of directors that includes external investors. For the founders and managers of some young firms it is a problem, indeed a dilemma, that resources for growth come at the cost of loss of autonomy.

The Firm in Its Selection Environment – the Issue of Fitness

The firm is not passive in relation to its environment as the founding entrepreneurs choose their business environment in selecting their business opportunity (Penrose, 1959). Evolutionary theory represents the firm's environment as the arena in which selection forces are exerted; these reflect the fitness criteria that are required of firms in that environment

(Nelson and Winter, 1982). Selection processes are experienced as the firm interacts with resource providers (including investors, the knowledge environment, and labor sources), coproducers, customers, and competitors and regulators. If they cannot find others prepared to do business with them, they are eliminated from that environment. There is scope for agency by the entrepreneurial firm, however, which can be proactive in a number of ways, including selecting a business mode and choosing activities and business partners best suited to a particular environment. For example, a venture producing solar cells may become involved in lobbying and standards setting, thus influencing the selection criteria in its environment. The following section examines the firm's coevolution with its environment as its ecosystem and business evolves.

Ecosystem Evolution

The firm's environment is likely to be dynamic; with continual changes taking place in the firm's input markets and its output markets. Important aspects of input markets include the allocation of resources by resource providers, and the prospects for coproduction with other organizations or of outsourcing. The growth and decline of product markets, and the changing level of competition, affect opportunities and firms' prospects (Utterback, 1994). Important features of the new firm's environment include the operations of the capital market that affect conditions of exit, merger, and acquisition. A key question in this respect is how firms coevolve with others in the markets and networks in which they operate, and this depends on how the firm is organized to create and capture value in its business environment. For example, in the early days of the fuel cell market, new ventures often were forced to develop the full spectrum of innovations and complements required for application, from fuel cell-specific components to hydrogen generators. As the industry matured and more companies entered the market, however, some firms began to specialize in hydrogen production, others in fuel cells for specific applications, and others in distribution.

Organizational Evolution

The business model provides a concept that bridges the internal organization of the firm and the way the firm organizes relations and transactions with external players in its business environment (Amit and Zott, 2010), which also can be viewed as a business ecosystem (Adner and Kapoor, 2010). As the organization emerges, it relies on an implicit or explicit business model to enable it to create value. The extent to which a firm can implement the business model depends also on what Teece (2007) has described as the 'microfoundations' of enterprise performance "… the distinct skills, processes, procedures, organizational structures, decision rules, and disciplines …" (p. 1319).

The firm's business model represents the way the firm is organized to create and capture value (Teece, 2010) and specifies the firm's role in the wider value chain or web. In developing a business model, decision makers are 'modeling' the conditions in which the firm will operate, its competitors, and it complementors in the innovation ecosystem, and on this basis, they are deciding how to create and capture value. A business model that allows the firm to create and capture value is a good fit with its firm's ecosystem.

Dynamic value creation and capture in a firm is developmental and occurs through economies of scope, resource building, and harnessing complementarities through benefits from partnerships. These are anticipated in a predictive business plan and are operationalized in the business model, which may be deliberate or emergent. In young firms operating under high uncertainty, business models are likely to evolve in unanticipated ways. Similar business models reflect similar responses to the business environment. For example, many ventures in biotech conduct early research and testing with close ties to university research, leaving marketing and distribution to the incumbent pharmaceutical firms that are likely to acquire them if their new medical entities are successful in clinical trials.

The selection environment may select differentially for value creation and value capture over the course of business cycles. For example, there was plentiful seed capital and venture capital for start-ups that were far from realizing profit during the Internet boom, but resources were withdrawn when the dot.com ventures failed to create and capture value by producing products and services and reaching profitability. Surviving Internet firms learned from these selection force effects. The business models of successful firms provide proxy evidence of selection requirements in that environment. If the firm is to succeed, its business model must meet the fitness requirements of the business environment. If a market economy is to succeed, market forces must exert selection criteria that favor organizations creating value for users and investors – not only over the short term but also over the longer term. If selection forces exerted by the financial system favor short-term value capture over value creation, this erodes the ability of emerging firms to create wealth in the longer term.

Alternative Perspectives on Early Firm Growth

There are two dominant approaches for looking at the emergence of new firms: the stages of growth process and the developmental process approach. These two approaches (e.g., Greiner, 1972; Kazamjian, 1988) both focus on dominant problems in the life of new firms. When considering stages of growth, Kazamjian (1988) distinguished six categories of dominant problems to growth in technology-based new ventures: those related to organizational systems, sales and marketing, people, production, strategic positioning, and external relations. When critical problems are solved successfully, the firm is able to continue to grow. This type of study focuses on taxonomies of problems in distinctive stages and assumes that firms progress sequentially across a specific sequence of stages.

In contrast, the developmental approach focuses on processes of change and feedback effects that influence those changes. If similar developmental problems are addressed in sequence through similar phases of activity, regularities will be

observed, but firms operating a different business model or engaged in different modes of activity will evolve differently (Garnsey, 1998). Regularities can be observed in companies producing similar products on the basis of similar business models (e.g., in early US computer hardware ventures). But the building of different kinds of resource base involves different sequences of activity – for example, developmental sequences in a research consultancy differ from those in a company producing medical instruments in house. Moreover, ventures may or may not inherit a resource base from another organization through demerger or spinout, and this will affect the sequence of activity required. On the basis of these considerations, we subscribe to a developmental approach, holding that there are no invariant phases of activity for all new firms as they emerge; instead, there are common requirements for development into an economically viable unit, but this can be achieved in a variety of ways.

Just as there are common developmental processes at work as firms solve common problems, there are shared constraints to growth. Metcalfe (1998: p. 45) identified five specific kinds of limitation to growth. Limitations can be "in relation to the ability to purchase inputs and sell output as determined by the growth of relevant market environments; in relation to the availability of internal and external finance to expand capacity; in relation to the managerial implications of growth for the ability to control costs; in relation to the growth of rival firms and thus the specific market of the firm; and in relation to the ability to imagine and articulate growth opportunities" (Penrose, 1959). According to Metcalfe (1998), all of these elements come together to determine the economic fitness of the firm.

Conclusion

This article has discussed how new firms move from recognizing or creating a business opportunity to becoming a viable market actor, and it considered how they evolve as organizations. This leads us to consider avenues for further study and practical policy recommendations.

Economists examine the growth performance of new firms in the aggregate but do not enter the 'black box' of development processes within the firm. Entrepreneurship studies examine case histories, events, and situations, but they fail to set the firm in a wider context, which makes it possible to identify what features are specific to that case and what is an instance of more generic developments found in other cases. Strategy studies have only recently begun to address the issue of new firms and their growth; this issue increasingly is being addressed in terms of the business models of new organizations, the final topic of this article. Although the orthodox study of industry structure is relevant to understanding the business environment of new firms, the approach is too static to deal with the dynamic nature of the environment facing many new entrant organizations. The study of how organizations emerge shows the need for enterprises to adopt a dynamic approach to strategy (and the business models that operationalize strategy) in new organizations.

Policy interventions should consider the coevolution of the firm and its environment. Policy makers who aim to promote thriving new firms should ensure that markets and regulators are applying selection criteria that promote sustainable value creation by new firms. These include the availability of finance to cover the costs of start-up and early development before the firm can create value. Beyond competitive selection forces, partnerships are needed to enable newcomers to do business with established players in clusters and strategic alliances that promote open innovation. In the absence of such conditions, firms are unlikely to develop sustainable business models or to grow to a size at which a significant number of new jobs can be created.

Organizational Errors: Catastrophic

Karlene H Roberts, Berkeley University of California, Berkeley, CA, USA

Abstract

This article discusses a relative newcomer to the social and behavioral sciences, the study of organizations in which errors can have catastrophic consequences. As we design ever more complex and technologically advanced organizations we create more opportunities for catastrophic error. The piece discusses precursors to present day social science research beginning with the sociological examination of the devastation of most of Halifax, Nova Scotia by an explosion in 1917. According to psychologist, Barry Turner, until 1978, the only interest in disasters was in responses to them. Today interest has broadened to include precursors, preventive strategies and mitigation.

The Past

Researchers and practitioners alike usually view accidents as slips, trips or falls. They then proceed to find the perpetrator and name, blame, train, or fire that person. Slips, trips, and falls, while taken seriously by their victims, are not usually harmful to the organizations in which they occur. Some accidents are seriously harmful to organizations. Take, for example, the 2010 BP oil spill in the Gulf of Mexico which flowed unabated for three months and may continue to seep. That accident killed 11 men, injured 17 others, and spilled 4.9 million barrels of crude oil (National Commission, 2011).

While catastrophic errors, risk, and reliability improvement have long been subjects of interest to practitioners and engineers, interest in these phenomena is newer in the social sciences. The first sociological approach to understanding accidents was Prince's (1920) dissertation on Canada's worst catastrophe, the 1917 munitions ship explosion in Halifax (Turner, 1978). This was the largest man-made disaster in the world to that date. Prince concentrates only on its aftermath. Prior to dropping atom bombs on Hiroshima and Nagasaki, the U.S. government used the Halifax accident to try to predict the sociological outcomes of these events.

In the United States just after World War (WW) II the sociological approach to the study of risk and catastrophes is primarily associated with E.L. Quarantelli and his colleagues. The many consistent themes in their publications include the myths of disaster behavior, the social nature of disaster, adaptation of community structure in the emergency period, dimensions of emergency planning, and differences among social situations that are conventionally considered as disasters (Dynes et al., 1994). The work primarily contributes to the sociological literature on collective behavior and social movement theory, and its focus is on how rents in the social fabric caused by a disaster can be repaired. In his seminal book, *Man-Made Disasters*, the British psychologist, Barry Turner, notes that until 1978, the only interest in disasters was in responses to them, and this was certainly true of the research mentioned above.

A corollary development that began during WW I was a focus on human factors which is a merger of engineering and experimental psychology. At first this field focused on finding men to fit systems. Later the field moved to examine both system and people characteristics which would allow the maximal match between men (and presumably later women) and systems. Such interests contributed to the psychological literature on occupational safety, which had a 'slips, trips, and falls' character.

Process safety emerged as a separate field from occupational safety in the 1980s (U.S. Department of Labor, 1994). It initially focused on understanding and explaining the nature and causes of major accidents and then on estimating their impacts. An emphasis was placed on plant and equipment design, which led to quantitative risk assessments that focused particularly on equipment failures. A focus on safety auditing systems resulted from the recognition of the importance of humans and was promoted internationally in the 1990s. Many industrial communities employed probabilistic risk assessment processes with increasing intensity until the early 1990s (Stamatelatos, 2000). Then these communities began to understand the limitations of such processes and search for improved ways to assess and manage the risks of their enterprises. These limitations were centered on the unpredictability and uncontrollability of the multitude of complex factors and interactions that determined the real risks these systems faced and on organizational factors.

Today such accidents are increasingly labeled 'process accidents.' They seriously disrupt or destroy the organizations in which they occur and ensuing clean-ups are hugely expensive. Such accidents are almost always rooted in the organization's fabric, and most often they have long periods of latency. An example is United Airlines DC-10 Flight 232 from Denver to Chicago on 19 July 1989. The plane suffered an engine failure and hydraulic system destruction and crash landed in Sioux City, Iowa, killing 115 people. 185 people survived. The engine failure was later traced back to a manufacturing defect in the fan disk, a defect that should have been discovered many times during regular aircraft maintenance (National Transportation Safety Board, 1990).

Recent Approaches to Error

There is a foreboding that these kinds of catastrophic accidents are on the rise. Man- and woman- kind build and try to manage ever more large and complex organizations. Greater size and complexity are associated with more errors that can have catastrophic consequences. Behavioral science researchers are

 http://dx.doi.org/10.1016/B978-0-08-097086-8.73126-6

increasingly concerned with finding ways to avoid such accidents or to mitigate their effects. Doing this requires the development of new conceptual and theoretical bases on which to understand the causes and consequences of such accidents. While this work has been ongoing since 1985 (see for example, Rochlin et al., 1987) it is still nascent.

There are two dominant approaches to understanding and avoiding catastrophic accidents. One is called high reliability theory (HRT) and the other normal accidents theory (NAT). HRT recognizes that some organizations in which catastrophic errors should occur, seem to avoid them and tries to understand how they do so. The underlying NAT logic is that if an accident can occur it will. Research from the first perspective focuses on such organizational processes as decision making, communications, how the organization is structured, etc. Research from the second perspective examines underlying potential causes of failure.

Both approaches suffer from the non-falsifiability problem. In neither case can you support the approach by showing how many accidents did or did not happen because no one has decided on the number of accidents or successes that would prove or disprove the theory. That NAT and HRT should be seen as competing theories seems silly to high reliability researchers. The competitive view began with the publication of Scott Sagan's book, *The Limits of Safety*, in 1993. He says:

> The first is the optimistic view of… "high reliability theory" whose proponents argue that extremely safe operations are possible, even with extremely hazardous technologies, if appropriate organizational design and management techniques are followed. The second school … "normal accidents theory" presents a much more pessimistic prediction: serious accidents with complex high technology systems are inevitable. (p. 13)

Clarke compares the two approaches in his review of *Limits of Safety* (Sagan) and *New Challenges to Understanding Organizations* (Roberts, 1993). He says:

> Sagan poses his central concern thus: "There has never been an accidental or unauthorized detonation of a nuclear weapon, much less escalation to an accidental nuclear war. Why?" The short answer: mainly luck (Clarke, 1993: p. 676).

About high reliability organizations(HRO) Clarke says:

> How do HROs do it? In my view, the force of the theory, as presented by HRO authors, is in a cultural factor and two structural ones. The cultural factor is represented by the metaphor of organizational learning; the structural factors are functional decentralization and redundancy (Clarke, p. 679)

Clarke then goes on to criticize both the HROs and the authors who discuss them by stating that both are filled with deception. Clarke concludes by pointing out that we need new ideas more than new data, and feels that Sagan provided those new ideas.

In 1994, the *Journal of Contingencies and Crisis Management* (vol. 2) published a four paper symposium airing the differences between NAT and HRO proponents. In a back and forth between Perrow (1994) and La Porte (1994) and then La Porte and Rochlin (1994) each author made his case. The basis of Perrow's argument is that technologically advanced organizations that can do harm to people and their environments are tightly coupled and complex. This combination of tight coupling and complexity leads to their failure. He also argues there are ways to minimize risk but that in the end complexity and coupling will doom the organization. Elite group interests and power, Perrow continues, allow the few to impose risk on the many for the benefit of the few. Under these circumstances, the elite may not do what is in the best public interest. Perrow concludes that the optimism of HRT is evidence that high reliability researchers do not consider power.

La Porte and then La Porte and Rochlin state that HRT and NAT are not competitive but complementary. La Porte and Rochlin say:

> …the HRO group takes as its starting point the perception by the organization that it is inherently susceptible to accidents, including very serious ones. We then attempted to find out what strategies have been developed by organizations that have demonstrated high levels of performance in the face of demanding conditions…. (p. 221).

Sagan (1994) is the bookend to this symposium. He agrees with Perrow and then offers suggestions for future research. He says that the pull of power and interests in organizational politics might complicate matters and should be included in research. He adds that we need much more study of redundancy. When does it backfire? When does adding more redundancy create common mode failures? And when does it add unreliability because individuals or subunits shirk their duties knowing that redundancy backs them up. Sagan claims that organizational learning is difficult in these advanced technological systems and suggests that perhaps introducing a political approach may uncover barriers to learning.

Since that time there have been a number of comparisons of NAT and HRO (e.g., and Leveson et al., 2009), and a number of attempts to merge the two approaches (e.g., Brady and Davies, 2010; Rosa, 2005).

In the 2000s more research has been devoted to teasing out high reliability processes and constructs than to unpacking NAT. This may be, in part, because results of early research on high reliability organizing were filtering their way into major accident investigations and major policy recommendations. For example, the *Columbia Accident Investigation Board's* (2003) discussion of organizational contributions to the accident is quite consistent with early high reliability findings. In 2008, the *Agency for Healthcare Research and Quality* (AHRQ) published a lengthy report entitled 'Becoming a High Reliability Organization: Operational Advice for Hospital Leaders'. AHRQ's mission is to support research to improve quality, safety, efficiency, and effectiveness in healthcare for all U.S. citizens. The report cites Weick and Sutcliffe's (2001) discussion of challenges organizations face that need to operate highly reliably:

Hypercomplexity. HROs exist in complex environments that depend on multi team systems that must coordinate for safety.

Tight coupling. HROs consist of tightly coupled teams in which the members depend on tasks performed across their team.

Extreme hierarchical differentiation. In HROs, roles are clearly differentiated and defined. Intensive coordination efforts are needed to keep members of the teams working cohesively. During times of crisis, however, decision making is deferred to the most knowledgeable person on the team, regardless of their position in the organization.

Multiple decision makers in a complex communication network. HROs consist of many decision makers working to make important, interconnected decisions…. HROs must develop processes that allow these decision makers to communicate effectively with each other.

High degree of accountability. HROs have a high degree of accountability when an error occurs that has severe consequences.

Need for frequent, immediate feedback. HROs exist in industries where team members must receive frequent feedback. This feedback and the opportunity to make continuous adjustments based on it are essential to anticipate and avert problems before they become crises.

Compressed time constraints. Time constraints are common to many industries… In HROs, the systems and culture allow people to identify when they lack time to reliably complete all needed tasks and obtain additional assistance (AHRQ, 2008).

The AHRQ report then goes on to mention the five reliability enhancing characteristics discussed by Weick and Sutcliffe:

Sensitivity to operations. HROs recognize that manuals and policies constantly change, and are mindful of the complexity of the systems in which they work. HROs work quickly to identify anomalies and problems in their system to eliminate potential errors. Maintaining 'situational awareness' is important for staff at all levels because it is the only way anomalies, potential errors, and actual errors can be quickly identified and addressed.

Reluctance to simplify. HROs refuse to simplify or ignore the explanations for difficulties and problems that they face. These organizations accept that their work is complex and do not accept simplistic solutions for challenges confronting complex and adaptive systems. They understand that their systems can fail in ways that have never happened before and that they cannot identify all the ways in which their systems could fail in the future.

Preoccupation with failure. HROs focus on predicting and eliminating catastrophes rather than reacting to them. These organizations constantly entertain the thought that they may have missed something that places people and their organizations at risk. 'Near misses' are viewed as opportunities to improve current systems by examining strengths, determining weaknesses, and devoting resources to improve and address them.

Deference to expertise. HROs cultivate a culture in which team members and organizational leaders defer to the person with the most knowledge relevant to the issue they confront. The most experienced person or the person highest in the organizational hierarchy does not necessarily have the information most critical to responding to a crisis.

Resilience. HROs pay close attention to their ability to quickly contain errors and improvise when difficulties occur. Thus, systems can function despite setbacks. An HRO assumes that, despite considerable safeguards, the system may fail in unanticipated ways. They prepare for these failures by training staff to perform quick situational assessments, working effectively as a team that defers to expertise, and practicing responses to system failures (Weick and Sutcliffe, 2001).

While HRO research began by in depth studies of three organizations that were identified as reaching or exceeding their reliability goals today both the contexts and issues in this research area have broadened. The first investigations were of U.S. Navy aircraft carrier operations, operating a commercial nuclear power plant, and the Federal Aviation Administration's air traffic control system. Today this kind of research is done in healthcare facilities (e.g., Vogus et al., in press), banks, mining operations, software firms (e.g., Vogus and Welbourne, 2003), the construction of Heathrow Airport's terminal 5 (Brady and Davies, 2010), etc. While early studies focused almost exclusively on organizational structuring, culture, and decision making, more recent studies examine such issues as conceptual under specification, measurement, counter factuals, organizational learning, team dynamics, etc.

W.R. Scott (1994) noted "one of the puzzling aspects of the growing literature on organizations prone to accidents…is the lack of connection to mainstream organization theory… the study of HRO needs to be better integrated into the study of organizations in general (p. 25)". As the research broadens out to include new issues it necessarily examines more mainstream organizational issues such as those mentioned above. Another criticism of the work is that it relies on case study methodology. That, too, has broadened out. We see a growing number of methodological approaches (e.g., Morgeson et al., 2011).

What's Missing

A major missing piece is action research that would provide managers and scholars with information about reliability processes that can be implemented with favorable outcomes. Most attempts at implementation of organizational research fail. In this area there is no scientifically based information on what to implement and how.

Today the research takes both micro and macro perspectives. It fails to take a systemic perspective. That is, it fails to examine the interdependencies of units or organizations working with one another, thus making the error of the third kind (Mitroff and Silvers, 2010), or solving the wrong problem precisely.

Returning to the BP example which opened this article, as night fell on 20 April 2010 a series of explosions rocked the semisubmersible drilling platform leased by BP from Transocean Ltd. The accident resulted in a sea floor oil gusher and is the largest accidental marine oil spill in the history of the petroleum industry. To date BP and Transocean have paid the U.S. Government approximately USD 9.2 billion in settlement fees (Reuters, 2013). A number of books have been written about the accident, numerous radio and television reports

were filed about it, Congress took testimony by parties to the case and a plethora of law suits were filed.

No one has examined BP in the context of its interactions with its regulatory agency, the Minerals Management Service (MMS), now the Bureau of Safety and Environmental Enforcement (BSEE), with its subcontractors, or with other companies in the same industry. Many large organizations are deeply interlinked with other organizations and understanding one organization in the set provides an incomplete picture. Some macro sociologically based organizational research does examine sets of organizations (e.g., network research, population ecology research) but those perspectives have not found their way into HROs research. It is unlikely to do so because of its perceived cost and the amount of effort required that would probably prevent any academically based researcher from further promotion.

What's Needed?

A number of things are needed to move this body of research along. Moving from the easiest to the more difficult approaches, work needs to continue to delineate what is meant by high reliability processes and to think about whether current labeling draws attention away from what we are really doing. Some writers have recently begun to differentiate between HROs (HROs, those that have reached this state) with reliability seeking organizations (RSOs) (Vogus and Welbourne, 2003). Unlike HROs, which operate high-hazard technologies, RSOs operate in high-hazard environments. RSOs are tightly coupled to their unpredictable and complex environments in such a manner that although the human mortality

> rate is low, the risk of small failures amplifying into organizational mortality is high. To cope with these environments, reliability-seeking organizations organize to remain open and flexible to emerging information and achieve the reliability demanded by their environments – intensity of innovation (Vogus and Welbourne, p. 877).

These differentiations focus attention on different associated processes. Research emanating from the HRO perspective is still in search of those processes associated with reliable performance. Research based on the RSO perspective focuses on processes involved with what we have to do to get there.

This leads us to think about taking a broader perspective on error by considering the language we adopt doing this kind of research. What do we call 'errors' and what do we call 'incidents'? These two words have different emotional pulls as do many other words we often use interchangeably in this line of research. This suggests a line of experimental research in which subjects evaluate the same incidents using different descriptive scenarios.

The role of emotions in high reliability organizing and in reliability seeking processes has, to date, been avoided. Yet, there is no doubt that different emotions are provoked in wildfire fighting, piloting aircraft in war time, the precision landing of aircraft, medical emergencies, operating complex technologically advanced equipment near their levels of maximum capacity, etc., than in product sales, housekeeping, and many other tasks done in organizations every day. We are long overdue in examining the roles of such emotions as guilt and shame in relation to reporting errors.

As yet there has been little effort to systematically examine the environmental requisites for highly reliable or reliability seeking organizations. The three organizations in the initial research are strongly regulated. When one moves to more market oriented organizations there may be no (e.g., healthcare) or weak (e.g., petroleum exploration) regulation. This undoubtedly influences an organization's attention to safety processes. Other aspects of the environment certainly influence how organizations think about reliability, such as the stock market, other external incentives, industry practices, etc.

Finally, research on organizational reliability is inherently interdisciplinary. Even within the social sciences both the journals and academic institutional arrangements are stove piped.

The problems requiring research solutions are not stove piped. Legal issues interact with organizational, personality, motivational, training, cultural, engineering design, and other issues. Looking again at the BP Gulf accident, all of these issues in addition to the systemic issues discussed would have to be examined to fully understand the accident.

Organizational Fields

Abstract

Organizational field scholarship illuminates the process by which globally accessible templates of behavior emerge and influence organizational action. An interest in understanding the sources of constraint for organizational adaptation lie at the core of this literature. Early scholarship focused on how the environment or institution shaped organizations. The institution determined whether fields were marked by stability or tumult. Alternatively, recent scholarship depicts a reciprocal relationship between fields and institutions placing greater emphasis on the ways in which interactions at the field level shape institutions. The organizational field remains a vital unit of analysis for detecting institutional effects and change.

Introduction

Is an organization free to adapt in any manner of its choosing? This question lay at the heart of any investigation situated within the organizational field literature. The empirical setting may vary from Fortune 500 companies (e.g., Davis, 1991) to city municipalities (e.g., Tolbert and Zucker, 1983). The topic of interest may range from defensive managerial practices (e.g., Davis and Greve, 1997) to maternity leave policies (e.g., Dobbin and Kelly, 1999). Yet, underneath these differences remains the same quest to understand organizational adaptation. By and large, organizational field theorists have concluded that even if they must and can do so, organizations are constrained in their ability to adapt. Customer preferences in the automotive industry may shift toward smaller more fuel-efficient vehicles. As US manufacturers can attest, however, years of investment in equipment, facilities, and relationships tailored toward large vehicle production present serious adaptive challenges. No matter how inclined an organization is toward change, the environment can erect insurmountable barriers.

Foundations

Perhaps the most oft-cited definition of an organizational field stems from Paul DiMaggio and Walter Powell's 1983 *American Sociological Review* article "The Iron Cage Revisited: Institutional Isomorphism and Collective Rationality in Organizational Fields." Drawing on insights from Max Weber's *Economy and Society*, DiMaggio and Powell (1983) sought to understand the modern-day sources of bureaucracy and rationalization among organizations. At the time, organization theorists primarily were concerned with explaining variation in organizational structure and behavior (e.g., Lawrence and Lorsch, 1967; Hannan and Freeman, 1977). Instead, DiMaggio and Powell (1983) proposed to explain the lack of diversity among organizational forms and practices, that is, they asked, "Why had organizations become so similar?"

In their quest to identify the forces driving homogeneity, focus went to the organizational field or "those organizations that, in the aggregate, constitute an area of institutional life: key suppliers, resource and product consumers, regulatory agencies, and other organizations that produce similar services or products" (DiMaggio and Powell, 1983: 148). Because it placed emphasis on the "totality of relevant actors," the term organizational field was ideal for understanding the sources of homogeneity as lying outside the boundaries of any one organization. Various actors, including the state, professional associations, and competitors exert pressures on organizations that over time lead them to adopt similar procedures, programs, and policies. Despite the existence of more efficient or rational ones, organizations feel compelled to incorporate practices solely because they have received the endorsement of important field members (Meyer and Rowan, 1977).

In his 1994 essay "Conceptualizing Organizational Fields," W. Richard Scott defined organizational fields as "a community of organizations that partakes of a common meaning system and whose participants interact more frequently and fatefully with one another than with actors outside of the field" (1994, pp. 207–208). Less concerned with explaining the sources of bureaucracy, Scott's definition highlights the relational nature of the interactions within fields and how shared understandings of a situation bind organizations to one another.

The conceptual definitions of organizational fields developed by DiMaggio and Powell and Scott have empirical implications. Both definitions highlight an aggregate of organizations, yet, otherwise offer few restrictions on what aggregates can and cannot be considered organizational fields. This lack of empirical specificity has resulted in a diverse array of organizational aggregates that have served as the empirical settings for field studies. Scholars have taken organizations listed on the Fortune 500 (Davis, 1991), the largest firms (Fligstein, 1991), organizations that share an interest (Hoffman, 1999), and geographically proximate organizations (Lounsbury, 2001) as members of a field.

Although scholarship on organizational fields experienced a renaissance during the past decades of the twentieth century, the concept had existed in one form or another for far longer within the organization studies tradition. Scott's imagery of a field harkened back to Ronald L. Warren's 1967 essay the "Interorganizational Field as a Focus for Investigation," published in *Administrative Science Quarterly*. Writing about community organizations, such as local banks, churches, and schools, Warren drew attention to situations in which organizations had dissimilar goals, yet found it advantageous to interact with one another to accomplish a given task like revitalizing a defunct business district. A shared understanding of the value of a thriving economic zone can provide disparate

organizations with a reason to work together. Warren's work in turn drew from that of Selznick.

Philip Selznick's (1949) study of the Tennessee Valley Authority exemplified not only the durability but also the evolution of the construct. Writing in the 1940s, like DiMaggio and Powell, Selznick concerned himself with the environment's effect on organizations, particularly its ability to constrain choice and agency. Yet, reflective of the time in which he wrote, Selznick's conception of the environment was locally rooted and understood as the interests, values, and attitudes of organizational constituents. For Sezlnick, organizations did not gain legitimacy by adopting practices deemed legitimate by some omnipresent forces within the field. Instead, organizations gained legitimacy by ensuring that their constituents' values and beliefs were reflected in the organizational goals. Here, the environment did not provide a generic template of action. No, the environment encapsulated people and groups with the power to change the agenda of an organization.

Within the more recent instantiations of organizational field scholarship, the environment has expanded. Technological advancements have made it such that local or even national borders no longer bind an organization's activities. Products made in one country are easily accessible to consumers in another. Employees seamlessly move between firms and across industries over the course of a career. Organizations exist within a globally defined and generated culture from which to draw templates of action (Weber, 2005).

Empirical Interests

Key to any investigation of organizational fields is the relationship between fields and the institutional literature more broadly. Although often thought of as interchangeable, organizational fields and institutions are in fact distinct. Defined as actions (Zucker, 1977), as facts that must be taken into account by social actors (Meyer and Rowan, 1977), and as the structures that provide stability and meaning to social behaviors (Scott, 1995, 2001), institutions are enduring features of social life (Giddens, 1979). At its core, institutional theory seeks to explain the process of institutionalization – that is, how actions, facts, or structures come to take on a rulelike status within society. Institutions structure an organization's environment (Meyer and Rowan, 1977), and within this paradigm, the organizational field serves as a level of analyses for investigating an institution's effects. Methodologically speaking, the organizational field becomes the unit of observation for analyses in which scholars ultimately hope to learn something about the institution.

Although subtle, the difference between institutions and organizational fields is important for it is through observations at the field level that we are able to learn about the effects of institutions. Many erroneously conclude that the primary takeaway from the organizational field literature is that fields are stable. Yet, organizational fields constantly shift. If fields appear at all stable, it is only because the effect of the institution in which these organizations exist is constant. Marquis' (2003) study of intercorporate networks demonstrated this quite well. Firms located in communities that began before the era of auto and air travel had more locally based director connections than firms located in communities that began after auto and air travel became prevalent. This result did not occur because there had been no change at the level of the field – many firms had entered and exited these particular communities. This result occurred because the cultural–cognitive templates or institutions that guided the construction of intercorporate networks remained constant within these communities.

Identifying the Effect of Institutions on Fields

Of particular interest to scholars concerned with investigating institutional effects has been exploring the mechanism proposed to account for homogeneity in structure and outcomes among field members. DiMaggio and Powell (1983) argued that coercive, normative, and mimetic forces led organizations to become institutionally isomorphic. A series of essays by Edelman (1990, 1992) provided a classic example of this investigative approach. Edelman sought to explain the proliferation of affirmative action and equal employment offices following the implementation of the employment-related sections of the 1964 Civil Rights Act. Through their professional associations, personnel officers touted the benefits of using bureaucratic policies to guide the recruitment and retention of women and minorities in the workforce. Nowhere in the act had Congress mandated that employers establish such policies. Yet, government authorities, including the Office of Federal Contract Compliance, the Justice Department, and the Equal Employment Opportunity Commission, came to view these policies as a necessary component in the fight to end employment discrimination. As a result, these policies and the offices overseeing them multiplied among organizations subject to the legislation.

Each of the three mechanisms thought to produce homogeneity played an essential role in the organizational response to equal employment legislation. Professional norms dictated that personnel officers respond to the uncertainty of the legislation in a particular manner. Once a critical number of companies had instituted bureaucratic policies and structures to oversee the hiring of women and minorities, other companies mimicked this behavior. As the bodies responsible for monitoring compliance with the employment regulations, agencies like the Office of Federal Contract Compliance and the court systems' endorsement of these bureaucratic policies and structures further exacerbated their use. The institution, primarily understood as regulatory agencies and courts overseeing these companies and personnel professionals working within them, encouraged the use of formal procedures to regulate the hiring and retention of women and minorities.

The perspective that institutions had a homogeneous effect on organizations dominated the literature for many years until scholarship on nuance and change emerged. Scholars such as Czarniawska and Jorges (1996) and Zilber (2006) challenged the theoretical understanding of diffusion within fields by arguing that organizational practices are not adopted intact, but instead are translated. Just as literal translations from one language to another often have no meaning, adopting a prevailing practice 'as is' will not work. Field members must

determine how to bend and shape a prevailing practice such that it will work given the particulars of their organizational context. Although some focused on complicating our understanding of the processes by which practices spread through fields, others looked to challenge our understanding of institutions as stable, inert entities.

Investigations illustrated that institutions vary, and support for particular organizational configurations are contingent. To illustrate, Kraatz and Zajac (1996) argued that for much of their existence, the institution – conceptualized primarily as student interest or consumer demand – called for liberal art colleges to prepare students for humanistic inquiry. As student career preferences shifted away from valuing liberal education toward a more occupationally rooted education experience, the institution no longer supported a focus on humanistic inquiry. Instead, the institution made it such that, to survive, liberal arts colleges had to institute vocationally and professionally focused courses (Kraatz and Zajac, 1996).

In a similar vein, building on the work of Friedland and Alford (1991), Thornton and Ocasio (1999) argued that institutions have historically variant logics. Economic and social structural shifts create a space for new logics to arise. As these new logics take hold, at the level of the field, organizational behavior changes. For instance, Thornton (2001) found that acquisition patterns within the higher education publishing industry varied according to the dominant institutional logic. When a market logic dominated the industry, publishers following an imprint or distribution strategy faced a higher risk of acquisition than others. When an editorial logic dominated the industry, imprint and distribution strategies had no significant effect on a publisher's likelihood of acquisition. As the logic changed, the pattern of acquisitions changed within the field.

In another instance, Scott et al. (2000) argued that between 1945 and 1995, institutional logics privileged particular organizational configurations for health care delivery over others. The authors linked the development of new organizational forms in the San Francisco Bay area health care field to the changing institutional environment. In the 1940s, hospitals represented the major organizational form within the field and with the exception of Kaiser Permanente no other health maintenance organization (HMO) existed. As the 1970s approached, however, HMOs became prominent within the field. The increased presence of HMOs corresponded to a shift away from a logic that privileged the professional dominance of doctors to one that privileged markets and the efficiency of service provision.

Identifying the Effect of Fields on Institutions

Scholarship pointing to nuance and change illustrated a more reciprocal process in which fields influence institutions and institutions influence fields. Field members have their own political and organizational interests (DiMaggio, 1988) that lead them to respond strategically to their environments (Oliver, 1991). As field members pursue their interests, the institution itself changes. This perspective has coalesced more recently under the rubric of institutional work. Key to this area of inquiry is the desire to challenge the conceptualization of field members as relatively powerless to resisting the isomorphic tendencies produced by institutions (Lawrence et al., 2009). Focusing on fields in this manner makes it clear that identifying the mechanisms responsible for producing homogeneity is not the only means by which to understand the relationship between fields and institutions. It is at the level of the field that institutions are created, maintained, and disrupted (Lawrence and Suddaby, 2006).

Focusing on the dynamics and consequences of the structuration process among organizations further illuminates the reciprocal relationship between fields and institutions. Structuration studies aim to understand how fields come together. Moreover, investigating structuration gives insight into how the process of field formation gives rise to particular institutional definitions. Hoffman's (1999) study focused on the development of the corporate environmentalism field. The actors within the field included petrochemical companies, environmental activists, regulatory agencies, investors, and insurers. As each actor entered the field, they brought their own understanding of corporate environmentalism to it. Thus, the process of field structuration became seen as not just a means to establish connections among the various actors – that is, creating the field – but also as a process that had implications for the definition of corporate environmentalism as an issue.

Likewise, Wedlin (2006) argued that the structuration process is about more than establishing connections among similar organizations. The structuration process acts as a mechanism that enables potential field members to debate and ultimately classify the organizations that should and should not belong to a given community. As the importance and desirability of certain organizational characteristics and attributes is weighed, the field's boundaries meld. To the extent that an organization is understood to possess the favored attributes, it can gain membership in this community. Consequently, the process of structuration leads to institutional definitions of organizational and field identity.

Conclusion

Initially developed to explain how external parties altered an organization's goal-setting apparatus, organizational field scholarship now illuminates the process by which globally accessible templates of behavior emerge as well as their influence on organizational action. Despite this shift in the literature, the interest in understanding the sources of and constraints on organizational adaptation remains at its core. Common across any investigation of organizational fields is the desire to identify the organizations, collectives, and individuals that interact with one another to produce some outcome – be it homogeneity or the development of a shared understanding.

Essential to this literature is the proposition that organizational action is contingent on the environment or the institution in which it resides. The institution dictates whether the organizational field is marked by the dynamics of rapid change or constant stability. Although historically dependent on itself, the institution shapes and molds the possibilities of organizations at the level of the field. Once conceptualized

as a unidirectional process, scholars now understand the relationship between fields and institutions as reciprocal. Institutions themselves are created, maintained, and disrupted through field members' interactions with one another. Accordingly, the organizational field remains a vital unit of analysis for detecting institutional effects and change.

Organizational Justice

Russell Cropanzano, Leeds School of Business, Boulder, CO, USA
Agustin Molina, University of Valencia, Valencia, Spain

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Research on organizational justice explores the psychological mechanisms by which people render judgments of fairness, as well as their responses to these perceptions. When workers believe that they have been treated justly, they tend to show higher job performance, better work attitudes, and lower levels of stress. With these benefits in mind, this article reviews the literature on organizational justice, placing emphasis on the different types of fairness, as well as interactions among these types. Individual-level and group-level approaches to justice are also contrasted, with special attention to recent theoretical and empirical developments.

Within the organizational sciences, the term 'organizational justice' can be understood as having two meanings, one narrow and one general. The narrow meaning refers to particular judgments concerning various types of events. When deciding whether an occurrence is just or unjust, individuals (or groups) ascertain whether or not it is morally appropriate. More generally, the term 'organizational justice' can also refer to scholarly literature. That is, it refers to a body of knowledge about these fairness evaluations, including such topics as how they are formulated, their dimensional structure, and their individual- and group-level effects.

In general, workers respond more favorably – both for themselves and for their employers – when they perceive that they have been treated justly. They respond less well when they perceive an injustice. Research has found that justice perceptions are positively correlated with organizational commitment, job performance, leader–member relations, and helpful organizational citizenship behaviors (OCB). They are negatively correlated with work stress, counterproductive work behaviors, and turnover intentions (Cohen-Charash and Spector, 2001; Rupp et al., 2014).

Descriptive vs Normative Justice

Within the organizational sciences, justice is generally studied descriptively. That is, it focuses on the perceptions or evaluations of fairness that are formulated by people at work. Put more starkly, an event is treated as 'just' or 'unjust' because some person or persons believe it to be. This approach is subjective and allows disagreement as to what is and is not appropriate. The descriptive paradigm taken by organizational justice researchers can be distinguished from the more familiar normative perspective that is often employed by philosophers. Speaking very generally, ethical philosophers use logic and observation to determine what is 'prescriptively' or 'normatively' fair (Cugueró-Escofet and Fortin, 2014). That is, philosophers seek to understand what the objective events or attributes are that make something just (Cropanzano et al., 2011b).

In practice, organizational justice researchers tend to borrow ideas from ethical philosophy. For example, seminal thinking on procedural justice was taken from John Rawls, and work on distributive justice traces back (at least) to Aristotle. Regardless, even when borrowing philosophical concepts, organizational justice researchers study them descriptively. For example, they are unlikely to emphasize whether, say, a voice procedure is truly fair, but are more likely to investigate whether people evaluate it as fair. Organizational justice scholars also study the consequences of having made a fairness judgment.

Forming Perceptions of Justice

This descriptive perspective favored by organizational justice researchers places a great deal of emphasis on individual perceptions of fairness. There are a number of different theories that attempt to account for how justice evaluations are formulated. However, most of these conceptual models share certain common features (Cropanzano et al., 2011b), which are reviewed here.

In most cases, individuals make fairness judgments when an event, and often one that is personally disappointing, occurs. To understand whether or not the event was unfair, rather than simply unfortunate or surprising, individuals make use of a comparative referent, which acts as a sort of moral yardstick. These points of comparison go by a number of names, such as 'norms', 'standards', 'rules', or even 'justice criteria'. When events are negative and inconsistent with these referent points, then people are apt to decide that an injustice has occurred. In short, individuals compare an actual occurrence to a normative standard and then evaluate the discrepancies (Hollensbe et al., 2008). As described so far, the formation of justice evaluations may appear to be somewhat simple and logical. However, this omits a number of complicating factors.

First, before people begin to appraise the fairness of an event, it needs to be salient. If it does not catch sufficient attention, then individuals will be less likely to do the cognitive work involved in formulating a fairness judgment. This is one reason why negative events that are surprising and personally relevant are especially likely to be viewed as unfair.

Second, in real-world settings people do not always go through the careful steps outlined above. Often, employees

simply model the behavior of their coworkers, thereby adopting the views of their peers rather than working out their own personal assessments. This is an important finding, which as will be seen is relevant to the formation of group-level justice perceptions.

Third, people differ as to who is and who is not included within their *scope of justice*. When other people are within this scope, such as in-group members, evaluators are more solicitous and scrupulous about applying fairness rules. Unfortunately, when others are outside the scope of justice, such as out-group members, then evaluators becomes less circumspect and more disinterested in how potential victims are treated. Findings for scope of justice may go far in explaining how observers can be nonchalant about the mistreatment of others. Fortunately, everyone does not show this effect to the same degree. The scope of justice effect is stronger for those with weak moral identities. Conversely, for individuals who see morality as important to their identity, this effect is weaker (Reed and Aquino, 2003).

Fourth, while people seem to care about fairness, they show considerable egocentric biases in their judgment. These biases can be automatic and unconscious. For instance, when individuals are assigned a side in a legal case, either defendant or plaintiff, and then asked to read about the alleged events, they show biased recall of facts and more extreme evaluative judgments. However, when individuals are told to read about the alleged events and only later assigned a role in the case, they show more accurate recall of acts and less extreme judgments (Thompson and Loewenstein, 1992). This suggests that personal relevance affects the processing of factual information.

Dimensions of Justice

Thus far we have described the precipitating stimuli for justice judgments broadly, using some terms as 'events' or 'occurrences'. In fact, justice scholars have devoted considerable attention to the types of things that people evaluate. Broadly speaking, these can be broken into three classes of event – outcomes (distributive justice), decision-making processes (procedural justice), and interpersonal treatment (interactional justice). Each of these is reviewed each, introducing alternative formulations where these are relevant.

Distributive Justice

Distributive justice refers to the perceived fairness of an allocation or, more broadly, to how people judge what they receive. It was probably the first type of justice to gain the attention of organizational justice scholars and continues to receive wide attention. In general, there are three rules that people can use to decide whether or not their outcomes are fair – equity, equality, and need (Deutsch, 1985).

Equity allocations treat a fair allocation as one that pays individuals in accordance with their contributions. There are different models of equity – Aristotle even had one – but by far the most influential is Adams' (1965) *equity theory*. According to Adams, individuals calculate equity comparing two outcome/input ratios. The first ratio is their own outcomes divided by their own inputs, while the second is a referent's outcomes divided by the referent's inputs. In order for equity to exist, these two ratios should match. A counterintuitive prediction of equity theory is that people care about overreward, as well as underreward. If an individual's ratio is larger than that of a referent person, this means that the individual has greater outcomes given his or her inputs. In such a circumstance, Adams found that the individual will attempt to restore equity by either raising performance (if pay is fixed) or lowering performance (if pay is piece rate). In general, equity theory has received support, including predictions for overreward. But it is not the whole story.

An equality allocation provides everyone with the same amount, without regard to contributions. Equality allocations are most likely to be used when the goal is to maximize group harmony; equity allocations are most common when the goal is to maximize productivity. As such, equality is relatively common among close, communal groups. There is some evidence that equality, as opposed to equity, is also preferred when decision making is allocating something negative, such as budget cuts. If we must share suffering, it seems that individuals often prefer to suffer by the same amount or percentage. Interestingly, equality may also have an information processing advantage, as it is a very simple allocation rule that requires less effortful thought than others. In this regard, researchers have documented the existence of an *equality heuristic*, whereby people simply divide things evenly unless they have the cognitive resources to consider a more complex norm (such as equity).

A third allocation rule is need, which provides outcomes on the basis of a perceived deficit. Perhaps surprisingly, need allocations have been less widely studied in the organizational sciences, although even profit-making firms make at least some use of them. For instance, family leave policies are allocated to those who need them – only people with particular needs (e.g., child care or elder care) receive time off.

In practice, when people are asked to make allocation decision, they often mix the rules together, such that they are not always used in a pure form (Cugueró-Escofet and Rosanas, 2013). For example, one strategy might be to provide 'necessities' or a minimum income to all. This would be an equality allocation. However, above this equal minimum the equity rule could be employed. In this regard, one might use merit to allocate additional payments. Another mixed approach might be to allocate different goods in different ways. Among American employers, for example, socioemotional goods indicative of group standing are often allocated equally, whereas economic goods are often allocated through equity (Chen, 1995). These and other sorts of mixed approaches seek to balance the strengths and weaknesses of the different allocation rules.

Procedural Justice

Outcomes need to arrive from somewhere. Procedural justice refers to the decision-making process or the set of policies that are used to make allocation decisions. For example, trials are one way that disputes are adjudicated in many societies. Research suggests that, to the extent that people perceive control within the legal process (e.g., they have 'voice', or the

opportunity to present their case), they are more willing to accept an unfavorable decision (Tyler, 2006). Interestingly, there seems to be marginal 'fairness returns' on at least some procedural safeguards. If a valued process is absent, then even small gains in its amount will boost perceptions of justice. However, at a certain point, some amount of the process appears to be satisfactory and additional gains will produce fewer benefits.

Leventhal et al. (1980) provided a list of six well-known criteria that are used to decide whether a procedure is just. In general, the process should treat all parties consistently, be free from bias, use accurate information in rendering decisions, take into account the views of all (something like voice), be correctable in the event of an error, and remain consistent with prevailing ethical norms. These six criteria have remained influential, although some additional rules might also be important in certain settings. For example, in some settings, people prefer advance notice before something potentially negative occurs.

Research reviewed by Tyler (2006) suggests that procedural justice place an important role in promoting citizen compliance with the law. When people believe that the political system is essentially fair, such as when citizens are adequately represented by their elected representatives, they are more likely to accept legal rules, even when these might not be viewed as personally desirable.

Interactional Justice

Bies (2001) has argued that in addition to formal outcomes and procedures, individuals evaluate fairness via social or communication criteria. That is, they look to how they were treated by others. Broadly defined, these social criteria have been found to fall into at least two categories (although there may be more than two) – interpersonal justice and informational justice.

Interpersonal justice pertains to the dignity and respect with which people are treated. An interpersonally fair transaction would avoid personal attaches, refrain from unnecessary harshness, eschew bigotry, and so forth. Some scholars have argued that this interpersonal variety of interactional justice has an especially unambiguous relationship to judgments of immorality.

Informational justice, as its names applies, refers to the provision of relevant evidence and explanations, and this is especially important when things go wrong. In particular, research has found that organizations should provide social accounts, indicating to the employee why things happen as they do. Such accounts are important (and surprisingly effective) in mitigating feelings of unfairness (Shaw et al., 2003).

There is some debate over interactional justice's structure. Many scholars combine interpersonal and informational justice together. This results in a three-factor model for fairness – distributive, procedural, and interactional. Others separate out the interpersonal and informational components, producing a four-factor solution (Colquitt, 2001). Both approaches seem to work psychometrically. Choosing between the three- and four-factor models may partially have to do with the goals of the researcher and the underlying theory.

Justice Rules in Real-World Settings

In general, fairness researchers argue for three or four families of events – outcomes, processes, interpersonal transactions, and information – that are appraised in accordance with a set of normative standards. While these standards certainly cover a broad class of situations, it is not clear that actual employees apply them as neatly as some research might imply. Some research suggests that decision makers supplement the better researcher approaches to justice with so-called emergent rules (Hollensbe et al., 2008). For instance, individuals may notice high turnover and work backwards to assume that this was caused by injustice. Alternatively, individuals might assess the level of supportiveness and use this to infer that a supervisor is fair. These emergent rules are important and should be the subject of future research.

Interactions between and among the Types of Justice

So far we have only considered the individual main effects of the different types of justice. Research has long supported the idea that the various types of fairness interact. For instance, individuals dislike receiving an unfair, or even unfavorable, outcome. However, the ill effects of an unjust allocation can be partially addressed if the allocation process is viewed as fair. For example, people who lose their court cases are unhappy with the outcome, but they are less likely to derogate the legal system if they perceive that it treated them fairly. Similar effects have been found for workplace decisions (for a review, see Brockner, 2002).

In general, the outcome by process interaction suggests that ill effects of fairness are maximized when both types of justice are low (e.g., low distributive justice + low procedural justice). Either type of fairness can buffer the effects of the other. Thus, it could also be said that individuals prefer to be provided with, say, voice, which is a characteristic of fair procedures. However, the absence of voice will not be problematic unless an outcome is unfair or at least unfavorable.

Despite these supportive findings, there are other times when a fair process is unlikely to ally the anger from an unfavorable outcome. A good example of this comes from research on 'moral mandates' (Mullen and Skitka, 2006). A moral mandate refers to a strongly held belief or opinion, which is grounded in an ethical judgment. A moral mandate would exist for an issue like abortion, when the debate is framed as an issue of human rights (e.g., the right to choose vs the right to life). For those possessing strong moral mandates about an issue, an unfavorable outcome is more difficult to mitigate by means of the procedure. Rather, the process itself is likely to be derogated as a result of the moral mandate violation.

Interesting, the two-way interaction works the same for interactional justice as it does for procedural justice. That is, interactional justice has the same buffering effects on unfortunate outcomes, and this has been observed in both the laboratory and the field (Brockner et al., 2003). This raises the possibility that any of the three types of fairness could allay the negative impact of the other two. By extension, this suggests that there should be a three-way interaction, such that the effects of unfairness are disproportionately present when all three are low. There is some evidence for this. Studies have

found that this three-way interaction predicts workplace retaliation and organizational attractiveness. At the present time, research on the three-way interaction is limited but promising, as the effect has been replicated (Cropanzano et al., 2011). However, less work has examined the four-factor model of justice in this way, although presumably this could be done as well.

Overall Justice

A recent trend within justice research, called *overall justice*, suggests that individuals form global judgments of how they are treated. Instead of focusing on the different sets of justice perceptions as three (or four) pieces of a puzzle, this approach allows researchers and practitioners to treat justice as a holistic assessment. The overall justice approach does not reduce the importance of the specific types of fairness. On the contrary, evidence suggests that overall justice judgments can be made in a 'bottom-up' fashion, as the specific justice perceptions are cognitively combined into an overall opinion. In other words, the types of justice act as the antecedents of overall justice judgments (Ambrose and Schminke, 2009).

Multifoci Justice

In the research viewed thus far, justice judgments have been treated as if they were directed toward a class of events, such as outcomes or processes. However, it is also important to consider the entity, such as an organization or a supervisor, who is the target of these appraisals. In this way, multifoci justice theory adds to this body of literature by evoking the importance of the *foci* or sources of justice. In the workplace, employees generally engage in social exchange relationships with multiple parties (Lavelle et al., 2007). Based on the nature of those exchanges, employees can form different perceptions for each of the sources of justice with whom they interact (e.g., customers, supervisor, coworkers, and the organization as a whole). Multifoci theory then highlights the importance of holding others accountable for the just or unjust acts that individuals experience in the workplace.

In short, research on this area has argued that employees can distinguish among different sources (Rupp and Spencer, 2006) and meta-analytic research has supported this contention (Rupp et al., 2014). For example, Rupp and Cropanzano (2002) found that employees form supervisory – procedural and interactional – justice perceptions. These authors further observed that those supervisory-focused perceptions could be differentiated from organizational-focused perceptions – organizational procedural and interactional justice. Another interesting finding from multifoci theory is that the relationship between a justice perception and a variable of interest will be stronger when the source of justice matches that of the outcome (Lavelle et al., 2007). If an organization that values its employees' commitment as core strength, for example, was worried about the impact of a new set of policies that have been implemented, the best approach to examine the antecedents on organizational commitment would be to measure its employees' perceptions of organizational procedural justice.

Group-Level Justice

The discussion so far has focused on individual-level perceptions of justice. In the workplace, though, individuals are constantly submerged within collective social structures. These may take such forms as teams, branches, and overall organizations. Justice scholars are no strangers to these structures or to their subjacent social dynamics. Over the last two decades, organizational justice has extended the scope of interest to include the appraisal of justice events and occurrences at the group level. Even though there are several arguments to describe the emergence of group-level justice phenomena, social information processing (SIP) theory and the attraction–selection–attrition (ASA) model represent the two approaches most used.

Social Information Processing Theory

According to the SIP theory (Salancik and Pfeffer, 1978), individuals do not work in isolation from one another. On the contrary, employees generally engage in social interactions to make sense of the events that take place during their daily activities. As explained in a previous section, employees may form justice assessments by simply modeling the behavior of their coworkers (Hollensbe et al., 2008). Consequently, as time goes by, the justice perceptions of each member of the group are said to converge. In other words, if group members receive similar outcomes, are subjected to similar procedures, and are treated in a similar fashion by a source of fairness (e.g., supervisor), over time, a shared judgment of justice emerges. In direct support of the SIP theory, Roberson (2006) demonstrated that the more time spent in sense-making activities, the higher the convergence of group members' procedural and distributive perceptions.

Attraction–Selection–Attrition Model

The ASA model (Schneider et al., 1995) posits that individuals with similar characteristics are attracted to, selected into, and retained by the same group. The first step, the *attraction*, suggests that individuals find organizations differentially attractive based on the congruence of the organizations' goals and their own personalities. The next step, the *selection*, concerns the recruitment and hiring of individuals who possess the desired attributives looked for by the organization. The final step, the *attrition*, argues that the employees who do not fit the organization will leave their work, whereas employees who do fit the organization will remain in their jobs.

Colquitt et al. (2002) were among the first scholars to provide evidence for the ASA model. These scholars observed that a characteristic such as the demographic – age, ethnicity, and gender – diversity within a team predicted the level of convergence among team members' perceptions on procedural justice.

Justice Climate and Peer Justice

Thanks to the advancements on multifoci theory, research on group-level justice has been able to distinguish between two

sources of justice from which shared perceptions can emerge. These are justice climate and peer justice. The former refers to how the unit believes that it is treated by an authority figure, while the latter refers to how teammates behave toward one another.

Justice Climate

Naumann and Bennett (2000) were the first to use the term *justice climate*. They referred to this construct as the shared perception of how fairly a group is treated by an authority figure – such as the organization or the supervisor. In their study, Naumann and Bennet measured the group's shared perceptions on the procedures enacted by the organization (i.e., procedural justice climate). Their results revealed that procedural justice climate predicted helping behaviors above and beyond individual-level perceptions of procedural justice. That is, the perception of the group explained a part of the helping behavior performed by employees that could not be explained by its individual counterpart (individual-level procedural justice). Several studies have been conducted since then attesting the importance of justice climate as a predictor of workplace attitudes (e.g., satisfaction, commitment), processes (e.g., citizenship behaviors, cooperation), withdrawal behaviors (e.g., absenteeism, turnover intentions), and unit performance (e.g., customer satisfaction, financial performance; Whitman et al., 2012).

Peer Justice

This construct refers to the shared perception regarding how individuals judge the fairness with which they treat one another (Li and Cropanzano, 2009). Peer justice thus examines how people who do not have formal authority over each other behave, or believe that they behave, internally to the group. Despite the novelty of this construct, peer justice has already demonstrated a great potential for the organizational behavior domain. Cropanzano et al. (2011a), for instance, showed that peer justice predicts task and interpersonal teamwork processes which, in turn, predict performance and citizenship behaviors. Similar to justice climate, the effects of peer justice were above and beyond the effects of its individual-level counterpart.

Justice climate and peer justice provide two key instruments for industries and organizations that keep increasing the importance of team settings. By measuring both constructs, researchers and practitioners can assess the full spectrum of group-level justice phenomenology. Whereas justice climate reflects the treatment the group receives from an outside person or entity, peer justice provides a picture from inside the group, shedding light on the internal social dynamics.

Concluding Thoughts

Organizational justice is an area of study that investigates how and why people come to form judgments of fairness in regard to their work settings. Justice scholars also explore the consequential behavior and attitudes that result from these evaluations. In general, justice perceptions can be organized into at least three broad families – distributive, procedural, and interactional – and also examined holistically. Justice perceptions can be directed at specific targets (multifoci justice) or formulated at the individual or group level of analysis. In all these ways, justice has been shown to be an important aspect of work life.

Organizational Path Dependence

Jörg Sydow and Georg Schreyögg, Freie Universität Berlin, Berlin, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Organizations are increasingly required to change rapidly and radically, i.e., to innovate or adapt to new circumstances in the technical and/or institutional environment. However, sometimes such organizational changes turn out to be extremely difficult, if not impossible. The theory of organizational path dependence features prominently in explaining this somewhat puzzling inertia. The antecedents, mechanisms, and outcomes of path dependence for organizations and interorganizational arrangements like alliances and networks are outlined.

Introduction

Why is organizational change so difficult, sometimes even impossible? We may almost expect large and bureaucratic organizations to be difficult to change, even in face of significant pressure from the technical and/or institutional environment (Amburgey et al., 1993). But this is much less obvious regarding smaller organizations or allegedly more flexible interorganizational arrangements like strategic alliances or regional networks. Nevertheless, under certain circumstances these may also become structurally inert or institutionally persistent. This is demonstrated by an increasing number of empirical studies (e.g., Maurer and Ebers, 2006; Manning and Sydow, 2011). The theory of organizational path dependence has been developed to explain these puzzling persistencies by highlighting the antecedents and mechanisms driving organizations and even networks into hyperstability.

The Theory of Organizational Path Dependence

The theory of organizational path dependence builds on earlier efforts in economics (David, 1985; Arthur, 1994) and political science (Mahoney, 2000; Pierson, 2000), and sets out to clarify the processes that lead institutions into a lock-in. Up until now, the explanatory power of the theory of organizational path dependence has been demonstrated in several empirical studies (e.g., Koch, 2011; Schreyögg et al., 2011; Burger and Sydow, 2014).

The basic point of any path-dependence argument lays stress on the importance of past events for current and future actions. This very basic insight has certainly advanced the building of a time-sensitive understanding of organizational phenomena, as well as helping to overcome the ahistorical, unbounded perspective of rational choice thought. Highlighting the fact that 'history matters,' however, is too vague a theoretical framework. In an attempt to develop a more specific understanding of path dependence, the drivers of the process have to be unearthed. The focus is on dynamics triggered by a critical event (or a sequence of events) that narrows the scope of action, eventually resulting in a state of persistence or lock-in. An important point of nearly all path-dependence thought is that this development need not be conceived as a negative spiral in terms of stabilizing an early bad decision or action pattern (as it is, for example, in the case of escalating commitment; cf Staw, 1984). In contrast, most path-dependence processes start quite promisingly; it is only later that the rationale changes and the development becomes disturbed by a dysfunctional flip. Path dependence, therefore, is inherently ambivalent in character.

With regard to antecedents, mechanisms, and outcomes of path-dependence processes in and among organizations, we have identified three different phases governed by three different regimes (Sydow et al., 2009). *Phase I* – the Preformation Phase – can be characterized by a largely unrestricted scope of action, where the choices taken cannot be predicted by prior events or initial conditions (Mahoney, 2000: 511). Up to a certain degree, however, the first phase is also influenced by the past: all choices are historically framed and therefore, in a way, 'imprinted.' Hence, we should refrain from conceiving this phase as a completely unrestricted choice in terms of rational choice models (as do David, 1985; Arthur, 1994; in their seminal works). The shadow in Phase I in **Figure 1** is intended to indicate this idea. Among the decisions made – on whatever basis – one choice may turn out to be a 'small event' that triggers further developments. From a path dependence point of view, this rather innocent or even random decision gains importance if, and only if it sets self-reinforcing processes into motion. At this point, nobody can predict that this initial action will end up in path dependence; this is only possible at a later stage of the process. At this point in time choices are still reversible, as well.

In *Phase II* – we suggest calling it the Formation Phase – the range of options narrows increasingly and it becomes progressively difficult to reverse the initial choice. In this – at least at the beginning, still quite open and possibly contested – phase of path-building, a new regime takes the lead: the dynamics of self-reinforcing processes. Arthur (1994) elaborates on these driving forces, conceiving them from an economic perspective as increasing returns (thereby excluding constant or diminishing returns as explanatory forces). On a general level, the notion of increasing returns highlights positive-feedback processes in which the increase of a particular variable leads to a further increase of this very variable. The notions of increasing returns or positive feedback indicate self-reinforcing processes with growing benefits when using a specific pattern of action or routine. There is a dynamic of doing more of the same. Eventually, a dominant organizational

Figure 1 The constitution of an organizational path. Sydow, J., Schreyögg, G., Koch, J., 2009. Organizational path dependence: opening the black box. Academy of Management Review 34 (4), 692.

solution emerges. The other side of the coin is that the whole process is becoming more and more irreversible: all alternatives are excluded more and more cognitively, and also materially in terms of investments. Decision processes or action patterns in Phase II are still contingent, however; i.e., while essentially constrained, choices are still possible. As David (1985) put it, the processes are 'nonergodic,' i.e., they are not accidental, but do not yet fully converge to a fixed point of distribution.

In the economic and institutional studies mentioned earlier, several types of self-reinforcing dynamics have been identified to date. Among them are (1) coordination effects, (2) complementarities, (3) network externalities, (4) learning effects, and (5) adaptive expectations. As empirical studies show, they are relevant in the organizational context as well (e.g., Schreyögg et al., 2011; Burger and Sydow, 2014). However, they may be of different importance there and act in a slightly modified manner.

1. When explaining organizational path dependence, the *coordination* effect features most prominently. Building on the benefits of rule-guided behavior, this effect relates to the heart of organizational theory: the more actors adopt and apply a specific institution (a law, a norm, a routine, etc.), the more efficient the interaction is among these actors, as their behavior is guided by a rule and can therefore be anticipated, and so on. In consequence, the more returns there are from sharing a rule, the more attractive (beneficial) it becomes for other people to adopt and so follow this very same institution.
2. Similarly important when explaining organizational path dependence are *complementarity* effects (see also Dobusch and Schüßler, 2013). These result from synergies from the interaction of two or more separate but interrelated resources, rules, or practices. In the case of complementarities, the advantages of repeatedly combining interrelated activities do not simply add up, they produce an additional surplus. In complementary settings, self-reinforcing processes occur when routines and/or practices are interconnected in such a way that it becomes more and more attractive to exploit the synergies or – when referring to the reverse aspect – to save misfit costs caused by solutions deviating from the established organizational capability. As a result, distinct sets of activity patterns become progressively dominant and deeply embedded in an organization ('deep structure'), i.e., they become organizationally path dependent.
3. Self-reinforcing effects are also brought about by *direct and indirect network externalities*. A user's benefits from a purchased good or service increase overproportionally, the more other actors use the same good or service too. For example, the purchase of a telephone was all the more rewarding the more others decided to use this device as well. Or in the case of video technology, replicating the initial choice for a system (e.g., VHS) was more rewarding the more people were already using this technology (Cusumano et al., 1992). This effect becomes even more rewarding and dynamic if indirect externalities exist too, i.e., the demand becomes even more focused because complementary products and services accompany the focal product – as was, for instance, the case with video stores, video recorders, and so on, in the case of VHS. These returns eventually led to a dominant solution irrespective of the fact that the first users had chosen that solution accidentally and a technically more advanced solution was available.

   This effect works in an intra- or interorganizational environment as well. Take, for instance, knowledge management systems. They work better the more employees (possibly also including participants from other organizations) subscribe to them, and it is more attractive to join the network the more employees use it already and the better it fits together with other information systems (e-mail, portals, etc.).
4. The *learning* effect holds that the more often an operation is performed, the more efficiency will be gained when operating subsequent iterations (Argote, 1999). The operations are performed more skillfully (faster, more reliable, and with less errors), which, in turn, means a decrease in average costs per unit of output. And the more attractive the chosen

solution becomes due to accumulated skills and decreasing costs, the less attractive it will be to switch to new learning sites (where the actors would have to start from scratch). Only sticking to the once chosen solution promises continued returns – although, as is well known, the resulting cost curve flattens after a while.

Self-reinforcing learning effects can be found on various organizational levels. One well-known example from organization-level learning indicates that a focus on the advantages of exploitative learning may increasingly drive out explorative learning (March, 1991). For various reasons (e.g., prevailing organizational culture and reward system), the motivation to improve everyday practices is likely to gain further acceptance or legitimacy (and thus more rewards) from the organization, whereas the motivation to look for fresh alternatives and to examine well-established organizational practices critically will shrink progressively.

5. The self-reinforcing effect of *adaptive expectations* originally relates to the interaction of demand and preference: i.e., preferences are not considered to be individually fixed, but rather vary along with expectations of what others do. Often-quoted examples highlight the need for social belonging and the desire to end up on the side of the winners. The first is best known as the bandwagon effect, stating that people trust in the wisdom of the majority. The more people purchase a particular good (and not another one), the more attractive it becomes for new buyers (Leibenstein, 1950). Users are uncertain about the right choice and feel rewarded by the fact that others have bought or will buy the same good or service – and the more the better. Because of these increasing returns, a dominant solution is likely to emerge (in most cases on the basis of more or less accidental first choices). The diffusion of a best practice in organizations often follows the same logic; organizational members are willing to adopt a practice because they expect others to do the same – a tendency which is also driven by legitimacy seeking. Subsystems not subscribing to the best practice run the danger of losing legitimacy.

A similar expectation effect stems from the desire to avoid getting into a failing position (e.g., Haller and Norpoth, 1994). Prospective users choose those options which they expect to win (in internal resource allocations, for instance). The more actors exchange and share this expectation, the more others will subscribe to the solution which is generally assumed to be the winning one. The more individuals adopt this expectation and base their choices on it, the more probable it is that the favored solution will gain the winning position – and the more rewarding it will be to join the winning solution. In other words, the emerging dominant solution stems from a self-fulfilling prophecy and its increasing returns for those who always want to join the winner's side (Pierson, 2000). In organizations, this effect can often be observed in political processes and coalition building. Once a suggestion by a group turns out to be successful, other organizational members are likely to join this group in order to avoid getting into a failing position.

As already indicated, most of these effects have originally been modeled in a restricted economic way, i.e., they develop only if the decision to reproduce a particular option is suggested by a utility maximizing calculus by an individual in terms of increasing returns. Without excluding this case, it seems too restrictive a starting point for an explanation of organizational paths. As is well known from a long-standing tradition in organizational research, there are also other self-reinforcing patterns in organizations, for instance, based on emotional reactions, cognitive biases, or political processes. These dimensions have to be included when setting out to understand the specific dynamics of organizational paths. Our suggestion, therefore, is to broaden the scope of self-reinforcing effects by including all kinds of positive self-reinforcing feedback cycles. In addition, a broader perspective beyond individual decision-making is needed to account for the social setting in which the positive feedback processes are embedded. It is the broader organizational context that informs actors and presses for self-reinforcing processes (see also Koch, 2011).

Finally, it should be stressed that self-reinforcing effects are not fully separate; rather, they often occur jointly and overlap (see also Dobusch and Schüßler, 2013). Take, for instance, information and communication technology, where the value of a specific terminal and the whole network depends to a large extent upon the number of users subscribed to this system. These direct network externalities are complemented by indirect network effects when the system is compatible with other already available technologies (printers, software, etc.), which are likely to generate synergies (complementarities). These effects can, in turn, be reinforced through increasing returns resulting from learning in the form of economies of scale: the increasing number of system users allows for a higher volume and, hence, declining costs per unit. These savings may be forwarded (partially) to the buyer – via lower prices – which will increase the attractiveness of the system even further. Adaptive expectations can speed up the spiraling process: prospective buyers observe the trend toward a particular solution and are therefore likely to choose the same system, thereby encouraging other potential buyers.

The transition from this second phase to *Phase III* – the Lock-in Phase – can be characterized by a further constriction which is likely to (but will not necessarily) lead into a lock-in, i.e., the dominant pattern gets fixed and even gains a quasi-deterministic character. Further decisions or actions are bound to the organizational path that has emerged; even new entrants have to adopt it. A lock-in means that the path has led the organization into a situation of irreversibility; actually, alternative organizational solutions cannot be realized. A lock-in is not necessarily inefficient in the beginning, but it is always problematic from a strategic perspective that requires organizational flexibility in increasingly 'turbulent fields' (Emery and Trist, 1965). However, the problem of a lock-in, even from a short-term perspective, becomes obvious in cases where a more efficient alternative appears but a switch is no longer possible. The result is actual or potential inefficiency. Therefore a major element of the third phase is (potential) inefficiency.

Considering specifically organizational paths (particularly in contrast to technological paths in a market), it may however be inadequate to conceive the third phase as a situation of total rigidity (or monopoly) in terms of one solution; a somewhat modified conception of lock-in seems to be required here.

Due to their social character, organizational processes are more complex and ambiguous in nature than market standardization (Cyert and March, 1963). They are not likely to amount to a concrete monopolistic solution that excludes any further choices. Rather, they are prone to bring about a specific action pattern that gets deeply embedded in practice and replicated across various situations. Fixed recursive patterns of action, however, cannot be equated with determinism, as practices have to be reproduced, and all reproduction includes interpretation and at least some minor deviation (Giddens, 1984). For these reasons, we should, in particular with regard to organizations, refrain from reifying paths and attributing an objective quality to them. Instead of a fully determined lock-in, no matter whether cognitive, normative, or resource-based, a theory of organizational paths is well advised to conceptualize the final stage of a path-dependent process in a less restrictive way, leaving some scope for variation (similarly: Pierson, 2000; Martin and Sunley, 2006). By implication, it seems more adequate to conceive of the lock-in state not in terms of total rigidity, but rather as a matter of degree accounting for some variance in the actual practicing of the path. A corridor may serve best to illustrate this reasoning; the shadow in Phase III in **Figure 1** is designed to indicate this corridor.

In sum, the proposed theory – as shown in **Figure 1** – conceptualizes an organizational path as a historically imprinted social process that is initially, in Phase I, shaped by a contingent choice, possibly leading to a critical juncture triggered by one or several events. Phase II, the Path Formation Phase, is governed by a regime of positive, self-reinforcing feedback loops, constituting and setting up a specific pattern of actions (social practices), which gains progressive predominance against alternative solutions to such an extent that, at least potentially, it leads in Phase III into a lock-in, in terms of a pattern underlying actions and/or practices. Thus all three stages pictured in **Figure 1** are governed by different regimes allowing us to differentiate between the phases not only in the theoretical model but also in the empirical data. Though this model focuses on the organizational level of analysis, it may also be helpful to analyze path dependence on the lower levels of organizational subsystems or higher levels such as interorganizational networks or fields, and to explore the interrelationships among various paths (cf Sydow et al., 2012).

Organizational Path Dependence and Related Concepts

The theory of organizational path dependence only provides explanations for very specific kinds of institutional persistence and structural inertia. Therefore, it may be helpful to distinguish this particular explanation from institutionalization and inertia. Because of the important role of imprinting, in particular in Phase I of a path-dependent process, it is useful to elaborate on its distinctive features as well.

The concept of *imprinting* figures prominently among approaches that seem to address a process very similar to organizational path dependence (Johnson, 2007). Basically, this concept postulates that either the initial cognitive schemes or the competences of an actor, a founding entrepreneur or a team, for instance, or specific contextual conditions (organizational structure, financial crisis, etc.) at the time of founding imprint upon organizational processes at later stages and, eventually, amount to a replicated pattern. While there are doubtless striking similarities that lead one to either simply equate imprinting and path dependence or to conceive the former as a specific variant of the latter, the process of becoming path dependent is, however, governed by a different logic. First, the replicated pattern in the imprinting approach is ready-made at the beginning; it is a specific scheme that persists and continues to influence future processes. In contrast, the gestalt of an organizational path is not clear at all in the early stage; it is an unforeseeable product of later processes. Second, a theory of organizational paths – as opposed to the imprinting approach – has to explain the unfolding of the process of path formation, not only the reproduction of structural properties because of either efficiency or a lack of competition, or the presence of institutionalization processes (Johnson, 2007). Nevertheless, imprints doubtlessly play an important role in many organizational processes. In path-dependent organizational processes, they can, for instance, explain the restrictions in the Preformation Phase.

Another concept that shares striking similarities with organizational path dependence is *structural inertia*, which results mainly from the increased routinization of organizational processes over time (Hannan and Freeman, 1984). Like organizational path dependence, structural inertia implies the hyperstability of organizational arrangements in spite of environmental change. Routinizing of organizational activities is seen as imperative in order to guarantee efficiency, reliability, accountability, and, finally, survival in competitive environments. Inertia is, however, like organizational path dependence, a double-edged sword: it is considered as a precondition to organizational efficiency and legitimacy but it may at the same time threaten the organization's survival when it leads to a misfit with changing environmental circumstances. However, in sharp contrast to organizational path dependence, inertia occurs via the intended establishment of reliable organizational structures; there are no structural dynamics. It is a universal requirement that all organizations have to fulfill. And all organizations, especially when growing and aging, are also expected to become hyperstable and face difficulties in meeting new environmental challenges. Opposed to that, the suggested framework of path dependence does not apply to all organizations, highlighting only special cases.

Contextual shaping forces play a major role in *institutionalization*, which also seems to come close to path dependence (e.g., Scott, 2008). Not unlike structural inertia, the institutionalization of (inter-) organizational structures and processes is demanded by the environment of the system, in particular the symbolic-normative environment. In the institutionalization process, specific organizational elements become sedimented and taken for granted over time. Despite similarities, institutionalization is a much broader concept and does not address the systemic logic of the escalating reinforcement of an action pattern leading into an organizational path (see Berthod and Sydow, 2013; for a further elaboration of the similarities and differences).

Implications for Organizational Research and Managerial Practice

This article has suggested a theory of organizational paths that builds, on the one hand, upon the seminal works of David and Arthur in order to transcend a purely metaphorical use of the notion of path dependence. On the other hand, this theory goes beyond these works, first by specifying the regimes under which the process of becoming path dependent unfolds in and among organizations, and second by modifying important assumptions in the light of organizational research. While an uncountable number of studies have investigated the persistence of institutions and/or the rigidity of organizations and even interorganizational networks (e.g., Amburgey et al. 1993; Maurer and Ebers, 2006), only relatively few have so far adopted an analytical approach based upon (strict concepts from) the theory of path dependence as presented above (e.g., Koch, 2011; Schreyögg et al., 2011; Manning and Sydow, 2011; Burger and Sydow, 2014).

The implications for organizational research are straightforward: more processual and detailed studies, possibly even using ethnographic methods (Yanow, 2009), are needed to understand better how events trigger self-reinforcing processes that – at least potentially – lead organizations or even interorganizational networks into a lock-in; a situation that is always problematic, at least strategically. Such studies should also be used to develop the theory of organizational path dependence into a more general approach to path constitution that informs us about possibilities of path breaking, path forking, and even path creation (Sydow et al., 2012).

While management may be particularly interested in these last alternatives, we suggest – given the present state of theorizing – a more modest approach and a focus on monitoring and understanding processes of organizational path dependence, along with their more often than not hidden dynamics within and among organizations (Schreyögg and Sydow, 2010). Although it is tempting to wonder about possibilities of path breaking or even path creation, the present state of theorizing provides firmer ground for understanding organizational path dependence.

Abstract

Cultural approaches to understanding the modern organization date back to the Human Relations studies of the 1920s. To understand the phenomenology of the modern firm, cultural theorists have explored the roles of power and meaning in the social construction of rational, and just, organizational practices. Neoinstitutionalists have recently turned their attention to how organizational practices travel across time and space, the role of agency in the construction and sustenance of the cultural practices of the firm, and the microfoundations of meaning in organizational practice.

In organizational sociology, the tradition of examining the role of informal, cultural patterns dates to the 1930s and the Hawthorne plant studies that spawned the Human Relations School (Mayo, 1933; Roethlisberger and Dickson, 1939). As Barley and Kunda (1992) argue, there have been waves of rationalist and culturalist theories of management, and of organizations, since then. The social constructionist approach to culture that has come to dominate the field has its roots in single-organization studies exploring culture, and in psychological theories of cognition. First, the single-organization studies were pioneered by institutionalist Philip Selznick and his students (Selznick, 1957; Zald and Denton, 1963; Clark, 1960). They explored how members of an organization become irrationally committed to the organization's routines and practices. Their method was to chart natural histories of individual organizations, often nonprofits. They found that members develop a collective understanding of the utility, efficacy, and rationality of organizational practices, and overestimate the importance of particular practices to the organization's success. Experiencing an organization's routines, and playing a role in the replication of those routines, produces this commitment. Culture is at the heart of the process.

Second, James March and Herbert Simon (1958) pioneered the cognitive approach to organizational practice in *Cognitive Limits on Rationality*, drawing conclusions similar to those of the institutionalists, but from a base in psychology rather than from historical studies of individual organizations. They observe that managers seldom consider all available solutions to a particular problem, and describe how consciousness is shaped by life within an organization – how an organizational worldview emerges. When faced with a problem, people typically think of an analogous problem from the past and apply the solution used in that case. The menu of solutions that comes to mind, then, is a consequence of organizational experience. The culture of a firm is embedded in its routines and practices, and the collective understandings that emerge to support those routines and practices. Organizational culture theorists would later describe the same phenomena in the terms of cultural anthropology (Schein, 1996; Martin, 2002).

In organizational psychology, Karl Weick's theory of sensemaking suggests that there are shared rationales of action that we pick up through experience, and that we choose from among these cultural constructs to understand behavior in organizations. For Weick (1993, 1995), the interpretive frames offered by society, and by the focal organization, shape how the individual understands her own actions. People may make sense of their own actions retrospectively, describing their behavior as part of a plan (Weick, 1979: p. 194). Sensemaking is like cartography in Weick's view, in that there is no one best map of the world but many useful maps that people can use to make sense of their actions. In sensemaking, people assemble causal maps from bits and pieces of practice and theory: "What the world is made of is itself a question which must be answered in terms of the available conceptual resources of science at a particular time" (Fay, 1990: p. 36). Cognitive maps are derived from experience and institutions. These maps are shared. They are cultural.

The Phenomenology of the Firm

In suggesting that organizational theory undergoes swings from cultural to rational theories, Barley and Kunda (1992) challenge the view that knowledge about management is cumulative. They also challenge the prevailing view of the firm *c*.1970, which was functionalist. The dominant thinking was that economic laws determined 'best practices' and that those 'best practices' would come to the surface everywhere. If organizations look alike, it is because they are subject to the same laws of efficiency. In *Institutionalized Organizations: Formal Structure as Myth and Ceremony*, the seminal article in the new institutional tradition, John Meyer and Brian Rowan (1977) attacked this view, proposing a constructionist approach to understanding organizational practices and routines. Meyer and Rowan describe modern organizations as adopting structures that symbolize rationality and fairness, and describe those structures as 'myth and ceremony.'

Organizations adopt practices that embody myths of rationality to both trumpet their commitment to efficiency and achieve it. We socially construct reality generally by classifying behavior patterns, norms, and rules and linking them to myths of rationality. Meaningful social conventions thus shape behavior in organizations: "Institutionalized rules are classifications built into society as reciprocated typifications or interpretations" (Meyer and Rowan, 1977: p. 341). Firms come to look alike because they follow the same rationalized myths of organizing rather than because each divines the same laws of efficiency. New myths of organizational rationality spread like

fads, causing organizations to adopt, and reject, matrix management and quality circles en masse.

The intellectual foundations of this approach are found in phenomenology and symbolic interactionism. Selznick, March and Simon, and Weick suggested that experience with practices in organizations shapes cognition and understanding, but the phenomenologists and symbolic interactionists focused more on the collective construction of cultural meaning in society generally, and less on the cognitive responses of individuals. In so doing they prepared the ground for a truly cultural theory of the organization.

Symbolic interactionist Erving Goffman (1974) built on Durkheim's (1961[1912]) ideas about classification and meaning in premodern societies, found in *The Elementary Forms of the Religious Life*, to argue that in the modern world, the individual "is allotted a kind of sacredness that is displayed and confirmed by symbolic acts" and arguing that "a version of Durkheim's social psychology can be effective in modern dress" (Goffman 2005[1967]: p. 47). Meyer and Rowan (1977) made very similar arguments about the modern organization: that it has become a sacred realm, and a locus of myth and ceremony in modernity. They built on Peter Berger and Thomas Luckmann's *The Social Construction of Reality* (1967) in the lineage of Alfred Schutz's *The Phenomenology of the Social World* (1967 [1932]). For Berger and Luckmann (1967: p.20), the task of sociology is to grasp "the objectivations of subjective processes (and meanings) by which the *inter*subjective commonsense world is constructed." The inclination to assign objective status to intersubjective reality is characteristic of human society, they contend. In mystified, religious, philosophical, and rationalized social systems alike, individuals make causal connections on the basis of the wider system of meaning institutionalized in concrete customs. People participate in sustaining ideas about reality, and thus, "Knowledge about society is … a realization in the double sense of the word, in the sense of apprehending the objectivated reality, and in the sense of ongoingly producing this reality …. The sociology of knowledge understands human reality as socially constructed reality" (Berger and Luckmann, 1967: pp. 210–211). Like tribal societies, modern societies trace social conventions to forces in the wider universe. But where Durkheim described totemic societies as tracing social conventions to the will of the animistic totems, today we trace conventions to self-interest and natural laws governing markets and bureaucracies. Modern culture is highly rationalized, but in modern societies, cultural meaning is organized around science and artificial laws of nature.

In 1983, Paul DiMaggio and Walter Powell built on Meyer and Rowan's ideas, sketching the ways in which new rational customs spread across organizations. Sometimes governments, or other extraorganizational forces, encourage organizations to adopt new conventions ('coercive isomorphism'), as when federal regulators dictate school standards (Meyer and Scott, 1983). Sometimes professional networks that span organizations promote new conventions with theories of their efficacy ('normative isomorphism'), as when finance managers promote the portfolio approach to corporate diversification (Fligstein, 1990). Sometimes managers copy practices of successful organizations without an idea of what makes them work ('mimetic isomorphism'), as when the U.S. automakers copied Toyota willy-nilly in the 1980s.

Diffusion of management myths, or cultures, made organizations within sectors quite homogenous in the postwar period. In recent years, diffusion across sectors has made organizations in very different sectors quite homogenous (Meyer, 1994). The corporate model, in particular, has spread to nonprofits and government agencies, such that they all have CEOs and mission statements.

How Power Shapes Culture

Power theorists have incorporated cultural insights from social constructionists to explain how groups promote policies and practices that serve their own interests by depicting them as in the interest of all. In Neil Fligstein's (1996) political–cultural approach to the firm, belief in the efficiency of institutions comes from rational theorization by consultants, economists, and management theorists. When an external shock – a recession, a policy shift – destabilizes one broad management regime, entrepreneurial consultants and managers promote innovations that are in their interest, or in the interest of their patrons. Thus the powerful are most likely to be able to put their preferred alternatives into place. They hawk those innovations by theorizing them as Pareto optimal, rather than as promoting the interests of a particular group. Thus they actively engage in the social construction of rationality, but of a politically infused rationality. Once in place, the theory holds the innovation in place. The conglomerate model of the firm, then, was shaken by policy and economic shifts *c.*1980, and institutional entrepreneurs successfully promoted a new model rooted in ideas about 'core competence' in management (Davis et al., 1994; Fligstein and Markowitz, 1993). Fligstein's power theory, then, builds directly on the insights that Meyer and Rowan developed in their institutional approach to explain how culture and legitimacy reinforce particular organizational strategies, across the organizational field.

William Roy, in *Socializing Capital*: *The Rise of the Large Industrial Corporation in America* (1997), sketches a somewhat different theory of the role of power in the modern firm, but one that also relies heavily on culture. For Roy, the social construction of efficiency keeps particular corporate strategies in place. Public and organizational policies that are adopted to support the interests of particular groups become legitimated through rhetorical strategies and economic theories, and group power differentials thus become institutionalized and obscured.

For instance, Roy (1997) explains the wave of mergers at the start of the twentieth century not as a consequence of economies of scale, as leading capitalists came to explain it. The cause was the enforcement of antitrust, which led large firms to force their smaller competitors to sell out because they could no longer fix prices together. The dominant players that emerged jumped on the idea of economies of scale to explain the merger wave, as a way to justify the rise of oligopolies and refute the notion that big industrialists had destroyed their smaller competitors. Thus the theory of economies of scale got a boost, and helped to justify concentrated ownership even in industries that enjoyed no scale economies. For Roy, once this pattern was established, it became self-reinforcing, largely because people make sense of the world around them by attributing rationality to practices, explaining surviving economic

solutions teleologically, as a consequence of evolution and natural selection. The successful theorization of new organizational practices means that they no longer have to be actively supported by the powerful. They become taken for granted, and advantages to certain groups (in the United States, owners of large corporations) become institutionalized.

Comparative students of organizations have explored differences in organizational cultures across nations. Hofstede (1980), for instance, shows that across countries, orientations to authority, innovation, and cooperation vary widely. The national business systems approach traces broad differences in organizational patterns not only to the organization-level construction of rationality, but to the wider constructions of economic actors and institutions that the organization engages with (e.g., Dore, 2000; Whitley and Kristensen, 1996).

New Directions in Cultural Approaches to Organizations

In what follows, we examine contemporary trends in the study of culture and organizations. Scholars have been examining how institutions travel across organizations and countries. They have been exploring the role of agency in institutional change. And they have been delving into the microfoundations of institutional persistence and change. Cultural approaches to organizations have been flourishing in recent years. Studies have shown the utility of a cultural and institutional approach for understanding organizational practices, their origins, and their sustainability.

How Institutions Travel

Studies by organizational institutionalists in the 1980s were dominated by research into processes of diffusion, or how organizational practices spread across fields (e.g., Tolbert and Zucker, 1983; Baron et al., 1986; Hirsch, 1986). This literature was later critiqued for an overly deterministic approach to diffusion, spurring a number of theoretical refinements and reconceptualizations of how institutions emerge and spread (Sahlin-Andersson, 1996). Building on the standard diffusion model, Strang and Meyer (1993) highlight the importance of expert theorization of new practices in the diffusion process, and reassert the importance of culture in the spread of organizational practices. Moving even further afield, Czarniawska and Joerges (1996) explicitly reject the idea of diffusion, drawing from Latour (1986) to suggest instead a model of translation and adaptation. Organizations do not simply adopt innovations, they translate and adapt them to local cultures. What goes by the name of matrix management may be entirely different in two different firms. While offering distinct theoretical contributions, both of these research streams complicate the institutional model of diffusion, offering greater attention to the symbolic nature of institutions through a nuanced account of how ideas, meanings, and practices move across an institutional field.

Theorization

A growing body of work has developed to challenge the traditional model of diffusion (e.g., Kennedy and Fiss, 2009). This line of research suggests several ways in which culture shapes the spread of organizational practices, first arguing that emergent practices diffuse not only through relational connections (or patterns of interaction) but also through cultural connections, and second arguing that emergent practices will diffuse more rapidly when they are theorized (Strang and Meyer, 1993; Greenwood et al., 2002). While previous diffusion studies focused on direct relationships, Strang and Meyer (1993) highlight the importance of 'cultural linkage,' meaning that two entities belong to the same constructed social category. A number of studies illustrate the importance of these shared social categories. In tracing the history of student activism in the United States, Sarah Soule (1997) finds a particular protest tactic spread quickly between similar universities, or those that shared institutional characteristics such as prestige, endowment size, and institutional type.

Theorization provides an account of why some innovations diffuse rapidly while others do not. Diffusion is aided by theorization: "the self-conscious development and specification of abstract categories and the formulation of patterned relationships such as chains of cause and effect" (Strang and Meyer, 1993: p. 492). Theorization includes two parts, the specification of an 'organizational failing' or a problem that the new practice will solve, and a story about how the innovation bests existing solutions (Tolbert and Zucker, 1996). Theorization allows new practices to be more readily adopted by organizations, as elements or properties of the practices are simplified and their outcomes are clearly defined (Greenwood et al., 2002). Thus theorization links the preinstitutionalization phase of institutional change, where local innovations or new ideas emerge, with the later stages of diffusion and institutionalization.

Theorization has been shown to aid diffusion processes across a number of empirical settings (Greenwood et al., 2002; Strang, 1997). For instance, Kelly and Dobbin (1998) trace the emergence of corporate diversity management, arguing that personnel professionals retheorized politically contentious affirmative action practices as diversity management practices. By retheorizing and renaming existing practices, to break the tie to federal regulations and create a tie to a looming change in the demography of the workforce and customers, personnel managers created a new rationale for practices such as race relations training (now 'diversity training') and boosted their diffusion (Kelly and Dobbin, 1998). This study points to the role of professionals in theorizing organizational practices.

Translation, Editing, and Adaptation

Sharing this focus on the spread of organizational practices, Scandinavian institutional theorists offer another perspective on the role of culture in institutional processes, with great attention to meaning, interpretation, and local context. Organizations, like individuals, are culturally embedded and thus the ideational and material aspects of organizational institutions (practices and their meanings) are translated or altered as they move from one place to another (Sahlin and Wedlin, 2008). As institutions travel they are modified to fit the new context; translation allows for variation to emerge based on local culture (Boxenbaum, 2006). From this perspective, change is both emergent and dynamic, neither fully strategic nor simply

the result of environmental pressures, but rather "a blend of intentions, random events and institutional norms" (Czarniawska and Sevon, 1996: p. 8).

In developing an account of 'how ideas travel,' Kerstin Sahlin-Andersson (1996) proposes an editing process. In part a reaction to the 'automatic process' of diffusion sketched by DiMaggio and Powell (1991), Sahlin-Andersson's (1996: p. 92) approach aligns more closely with that of Friedland and Alford (1991) in their original conception of institutional logics. While Friedland and Alford (1991) argue that multiple, sometimes contradictory, institutional logics allow for organizational choice in selecting particular practices, Sahlin-Andersson (1996) argues that variation in local practices can be explained by the editing process whereby new models are not simply imported wholesale (or selected due to the logic they instantiate) but are modified through a process of adaptation. This process entails shifts in both the material and ideational aspects of institutions to align with local models and practices.

Studies of translation highlight the importance of viewing institutions as embedded and best understood in context. In tracing the spread of corporate diversity management from the U.S. to Denmark, Eva Boxenbaum (2006) finds that the process of translation involves: (1) individual preference, as some elements of the frame appeal to particular translators, (2) strategic reframing of the practice, to best appeal to interests of powerful actors whose support is necessary for implementation, and (3) local grounding, to match the framing of the practice to existing practices in the local context.

Agency and Institutional Change

Institutional theory has long been critiqued for neglecting or undertheorizing agency (Battilana et al., 2009; Powell and Colyvas, 2008; Barley and Tolbert, 1997). As DiMaggio (1988) argued, institutional theory must account for "the reality of purposive, interest-driven, and conflictual behavior" (1988: p. 5). Recent work on institutional entrepreneurship has demonstrated a range of field-, organization-, and individual-level factors that enable individual actors to change institutions (Battilana, 2006; Greenwood and Hinings, 1996; Greenwood and Suddaby, 2006).

Institutional Logics

The institutional logics approach, while clearly building from the neoinstitutional framework, takes a sort of middle ground in theorizing the link between agency and structure in institutional studies. Proponents eschew rational actor models by characterizing individual interests, identities, and understandings as embedded within logics, while at the same time describing actors as capable of overcoming institutional constraints to innovate (Greenwood et al., 2008). Critical of the institutional focus on isomorphism and the inherent stability of institutions, the institutional logics camp developed a metatheory and analytical framework that allows an analysis of the interrelations between institutions, organizations, and individual actors (Thornton et al., 2012). There are various institutional orders – family, religion, state, market, profession, and corporation – and there are elemental categories of institutions aligned to each, including sources of legitimacy, authority, and identity, as well as bases of norms, attention, and strategy (see also Boltanski and Thevenot, 1991). The logics approach views cultural content, the symbols and practices of each logic, as potentially complementary or contradictory. It is through transposing symbols and practices across institutional orders within an institutional field that change occurs (Thornton, 2004; see also Padgett and Powell, 2012).

While logics can be seen as constraining, in as much as an actor's social position makes particular logics more accessible, the fact that actors are exposed to multiple logics allows for agency. Individuals and organizations are part of multiple institutional orders, which provide both symbolic and material resources. Thus actors can combine logics, highlight contradictions, and otherwise reinterpret and mobilize meanings and practices to drive institutional change (Thornton and Ocasio, 2008). A range of empirical work supports these theoretical claims. Scholars have shown that more than one logic may be present within an organization (Lounsbury, 2007; Reay and Hinings, 2009). Individuals within organizations may mobilize elements of disparate logics. They can also make use of elements of old institutions. Dacin and Dacin (2008) study deinstitutionalization, finding that even while institutions decline, their remnants remain potent and serve to allow for the reemergence or reinvention of institutions. Actors play a key role here, serving as 'custodians' of institutionalized practices.

Microfoundations of Institutions

In concert with calls for revisiting agency in organizational institutionalism, there have been calls for increased attention to the microfoundations of institutionalization and the process by which the institutional environment shapes organizational practices (Zucker, 1977; Tolbert and Zucker, 1983, 1996). Studies of the microfoundations of institutions can be traced back to the origins of the field. Lynne Zucker drew from both the phenomenology of Berger and Luckmann (1967) and the ethnomethodology of Garfinkel (1967) in developing an argument for how institutions consist of taken-for-granted meanings (Zucker, 1977; Tolbert and Zucker, 1996). These same traditions shaped the thinking of Meyer and Rowan (1977) and DiMaggio and Powell (1991). As DiMaggio and Powell argue, "ethnomethodology and phenomenology together provide the new institutionalism with a microsociology of considerable power" (1991: p. 21). However, as Barley (2008) and others have contended, neoinstitutional theory has not provided adequate attention to issues of agency or practice. Recently however, there has been increased attention within organizational institutionalism to the importance of the interactionist approach (Fligstein, 2001; Hallett and Ventresca, 2006), the microprocesses of institutionalization, and organizational change at the microlevel (Kellogg 2009; Johnson et al., 2000). While Thornton et al. (2012) provide a theoretical account of microfoundations in developing the institutional logics approach, empirical work at the microlevel is scant.

Bricolage

Campbell (1997) draws the term bricolage from the anthropologist Claude Levi-Strauss (1963) to describe knowledge

creation that is put together piecemeal from a variety of sources. Baker and Nelson (2005) use the idea of entrepreneurial bricolage to explain that, rather than being constrained by their resource environments, certain firms are able to make use of specific physical (materials, skills, labor), social (customers and markets), and institutional (standards and regulations) resources that other firms lack access to. This approach suggests that resource environments, or fields, are socially constructed. Baker and Nelson problematize the view that resources are objective or clearly definable, defining bricolage as "making do by applying combinations of resources at hand to new problems and opportunities" (2005: p. 333). A growing body of work employs bricolage in explaining the emergence of hybrid practices (Campbell, 1997) and the creation of new political organizations (Clemens, 1993).

Institutional Work

Institutional work is "the purposive action of individuals and organizations aimed at creating, maintaining, and disrupting institutions" (Lawrence and Suddaby, 2006: p. 215). This bottom–up approach to how actions shape institutions seeks a middle ground between 'cultural dopes' in the neoinstitutional literature and the overly agentic institutional entrepreneur literature (Powell and Colyvas, 2008). The approach also bridges institutional theory and practice theory. The overarching claim of institutional work theorists is that institutions should not be viewed as taken for granted and stable. Rather, institutions require maintenance, not simply via their regulative and normative pillars but also via the cultural–cognitive pillars (Lawrence and Suddaby, 2006).

Zilber (2009) considers how broad, societal metanarratives are used to support and give legitimacy to local narratives. Here we see how local institutions are shaped, in part, by broader context. As Zilber demonstrates, institutional maintenance can also include elements of translation, as institutional metanarratives are translated into organization-specific stories (Zilber, 2009). Zilber highlights the importance of power, as organizational elites shape the organizational 'reality' through their storytelling and translation of societal metanarratives.

Marti and Mair (2009) adopt an institutional work perspective to study rural health care organizations, finding that actors borrow logics from multiple domains, such as cultural and religious domains, in order to drive change. They argue that this is not a case of bricolage, where actors borrow institutional elements from another field. Rather, actors must 'navigate subtly' between several distinct logics that operate in multiple domains. For instance, efforts to provide microcredit to women in the developing world must fit within the financial and business logic, but also link to distinct cultural and religious norms.

Institutions are composed of both material and ideational elements. Berger and Luckmann (1967) conceive of institutions as made of practices and meanings that became taken for granted through enactment. Meyer and Rowan's 'rational myths' are simply taken-for-granted parts of modern institutions. While the symbolic has been a central part of neoinstitutional theory, empirical work has focused more prominently on organizational practices or material elements than on meanings and the ideational elements (Zilber, 2008). Heeding calls for more attention to meanings, studies of institutional work may inform understandings of the cognitive underpinnings of institutions. However, the institutional work literature is quite new. Recent studies test particular types of institutional work sketched by Lawrence and Suddaby (2006), suggesting there is much to be done in fleshing out the theoretical model.

Conclusion

The study of organizations and culture is one of the most active fields in organizational sociology today. Institutional theory is based in the social constructionism of Peter Berger and Thomas Luckmann (1967). The perspective first set out in Meyer and Rowan's (1977) *Institutionalized Organizations: Formal Structure as Myth and Ceremony* and developed in discussions of theory (Meyer et al., 1987; Meyer and Jepperson, 2000), describes the modern worldview as a historical construct. So are organizations and their various routines and practices. Meyer and colleagues offer a radical challenge to the taken-for-granted categories of modernity and the taken-for-granted causal relationships. In Berger and Luckmann's (1967: p. 20) brand of social phenomenology, which Meyer and colleagues draw on, the task is to grasp how collective understandings of the social and physical worlds around us become objectified, such that we do not see them as collective understandings. They ask how our subjective 'knowledge' of the world comes to have the feel of objective reality. Berger and Luckmann focus on the different intersubjective realities found in mystified, religious, and rational settings. These realities emerge through experience, and at the level of cognition, the individual makes causal connections on the basis of the wider system of meaning institutionalized in concrete customs. Students of organizations and culture first built on these insights by tracing the spread of new ideas about management and the practices associated with them. They went on to explore the role of expert theorization, as modern-day witch doctors who call themselves sociologists, economists, and management consultants divine laws of the organizational universe and promote practices that conform to those laws. In recent years they have turned their attention to the cognitive processes, mental maps, institutional logics, and microlevel processes that undergird, and ultimately that produce and change, organizational practices and their meanings.

Organizations and the Law

Mark C Suchman, Brown University, Providence, RI, USA

Abstract

The relationship between organizations and the law is rich and complex. Organizations encounter law in at least three guises: Law as a *facilitative arena* for interaction; law as a *regulative code* for conduct; and law as a *constitutive schema* for experience. In each of these guises, law is simultaneously an independent variable affecting organizational activity and a dependent variable reflecting organizational activity. Moreover, whether as cause or as consequence, law operates simultaneously through material incentives and through cultural beliefs. This article explores the diverse body of scholarship on organizations and law that has emerged to make sense of this varied terrain.

Scholarship on organizations and the law addresses the relationship between formal organizations – such as private businesses, public agencies, and nonprofit associations – and the legal institutions that govern them. Since both organizations and law receive separate treatment elsewhere in this encyclopedia, this article concentrates solely on the connections between the two. These connections are elaborate and diverse, and different research traditions have explored different territories along three cardinal axes: First, various researchers have emphasized the relationship between organizations and at least three distinct aspects of law: (1) legal venues as *facilitative arenas* for organizational interaction (especially disputing), (2) legal precepts as *regulative codes* for organizational conduct, and (3) legal definitions as *constitutive schemas* for organizational experience. Second, the relationship between organizations and each of these aspects of law can involve multiple causal orderings: Law not only shapes organizational activity, but organizational activity simultaneously shapes law – and at times both take shape together. Third, for each aspect and each causal order, the relevant mechanisms may operate either through material rewards and punishments, or through cultural morals and meanings, or through complex mixtures of the two. The following pages examine the diverse images of organizations and the law that lie at the intersections of these cardinal dimensions.

Intellectual History

Classical Roots

Classical social theorists saw organizations and law as closely linked. To Marx (e.g., 1842, 1844), capitalist organizational structures provided the economic premises for 'bourgeois law,' with its characteristic coupling of formal individual rights – especially rights of property and contract – and repressive police interventions against the working class. To Durkheim (1893), society's evolution from a unified to a specialized division of labor (and the corresponding shift from communal to limited-purpose organizations) generated a parallel evolution in law, from punitive demonstrations of shared outrage to restitutive compensations for individualized damages. To Weber, 1978/1925: pp. 654–658, 956–1005), both modern organizations and modern law drew legitimacy from a shared 'legal-rational' reliance on purposeful, systematic, impersonal rules; and as a result, both embodied similar tensions between responsiveness and predictability, and between autonomy and domination.

Mid-Century Revival

Despite these early linkages, subsequent scholarship on organizations and on law developed for the most part independently. A few theorists (e.g., Hurst, 1964) attempted to bridge the gap, but most research in each tradition remained oblivious to the other. Since the mid-twentieth century, however, the separation between organizational and legal studies has become increasingly untenable. Organizations form through the legal act of incorporation, and they dissolve through the legal act of bankruptcy. In between, they raise capital under securities law, hire employees under labor law, and exchange goods and services under contract law. Law, for its part, arises from the demands of organizations, and it topples under pressure from organizations as well. In between, it develops meaning through organizational compliance, receives enforcement through organizational litigation, and encounters limits through organizational recalcitrance. Moreover, the organizational and legal worlds have become increasingly intertwined over time, as organizations experience rising levels of litigation, regulation, and certification, and as law grapples with an ever more bureaucratized society.

In light of these affinities, a reconciliation between organizational and legal studies was perhaps inevitable, and by the mid-1960s, the early signs of convergence were beginning to emerge. At least four distinct lines of scholarship contributed to this rapprochement: a political science literature on regulation, a sociology literature on legalization, an economics literature on transaction costs, and a legal literature on commercial contracting.

Studies of Regulation

From political science (and to a lesser extent economics and sociology), a number of researchers have explored the relationship between regulatory agencies and the industries those agencies supposedly oversee (e.g., Bernstein, 1955; Stigler, 1971; Posner, 1974; Peltzman, 1976; Hawkins, 1984; Kagan and Scholz, 1984). Although many such investigations have

started with the assumption that well-chosen penalties can deter organizational wrongdoing, the empirical evidence suggests a gloomier story: In what economists have labeled the 'market for regulation' (Ulen, 1980), industries often appear to 'capture' their regulators (Laffont and Tirole, 1991; Dal Bó, 2006), resulting in legal rules that limit competition and preserve prevailing practices, rather than imposing reforms. Moreover, even when agencies do attempt to regulate in the public interest, regulated organizations are less likely to be deterred from wrongdoing than to be impelled toward evasion. In recent years, the rhetoric of regulation has shifted away from top-down 'command and control,' toward a more collaborative philosophy of 'industry self-governance' (Lobel, 2004); however, even where regulation on-the-books conforms to the command-and-control paradigm, regulation in-action rarely looks so simple (Short and Toffel, 2008; *see* Regulation).

Studies of Legalization

The pessimism of the regulation literature has been counterbalanced by a second body of research, originating from sociology. Examining the emergence of lawlike organizational structures such as formal work rules and disciplinary hearings, Selznick and his followers (Selznick, 1969; Edelman, 1990; Dobbin et al., 1993) have suggested that administrative and political pressures can lead organizations to develop internal practices that draw upon the public legal order for models of fairness and objectivity. Over time, these introjections of legality tend to become 'institutionalized' – both within organizations as formal policies and procedures, and outside organizations as legal doctrines and statutes. The resulting 'legalization of the workplace' (Sitkin and Bies, 1993; Sutton et al., 1994), holds the potential to transform organizations from authoritarian hierarchies into normatively constrained polities, thereby limiting official power and securing substantial 'citizenship' rights for lower-level participants (Dobbin and Sutton, 1998; *see* Legalization).

Studies of Transaction Costs

In contrast to the literatures on regulation and legalization, a third body of scholarship, emerging primarily from economics, downplays concerns about making organizations more socially responsible and focused instead on making them more efficient. Drawing heavily on the work of Coase (1937) and Williamson (1975), this tradition links law and organizations through a set of generalizable arguments about the costs and benefits of 'hierarchical governance,' whether in the form of legal rules or organizational policies. Because human beings are only 'boundedly rational' (i.e., unable to anticipate all future contingencies) and 'opportunistic' (i.e., prone to self-interested dishonesty), certain recurring exchanges will exhibit sizable 'transaction costs' in the market: Detailed long-term contracts will be difficult to write and enforce, and hierarchical authority structures may consequently prove more efficient than market trading. Since organizations and laws represent alternative forms of hierarchical governance, this analysis speaks equally to the question of when the legal system should intervene in market activity and to the question of when organizations should internalize market exchanges (*see* Transaction Costs and Property Rights).

Studies of Commercial Contracting

Somewhat ironically, at about the same time that transaction cost economists began calling attention to the trade-offs between market contracts and hierarchical authority relations, a small group of legal scholars began calling attention to the remarkably minor role of formal contracting even in the market itself. Sparked by the empirical fieldwork of Stewart Macaualy (1963), and systematized in the 'relational contract' writings of Ian Macneil (1977), this tradition highlights the extent to which ongoing business relations give rise to informal norms of reciprocity, forbearance, and mutualistic decision-making that largely displace the right-versus-wrong, winner-take-all dichotomies of the formal law. Subsequent economic accounts have debated whether such 'incomplete contracts' (Hart and Moore, 1988) and 'private ordering' regimes (Ellickson, 1991; Bernstein, 1992) serve to minimize transaction costs. However, the original insight of the relational contract literature was less about economic efficiency than about social embeddedness: Most business commitments arise within preexisting organizational communities, where formally alienable legal rights often become inextricably entangled with identity-defining moral claims (Suchman, 2003). This proposition offers a sociological counterpoint to economic theories of 'transaction cost engineering' (Gilson, 1984), in much the same way that the legalization literature offers a sociological counterpoint to economic theories of the 'political market' for regulation (Peltzman, 1976).

Current Scholarship

In recent years, these four bodies of research have spawned a resurgence of scholarship on organizations and the law. This resurgence spans the disciplines of political science, sociology, and economics, with offshoots extending into traditional legal and managerial studies as well. The present section reviews the state of this emerging literature, with emphasis on the three major aspects of the legal environment introduced in the opening paragraph above. Following Edelman and Suchman (1997), these aspects are designated the 'facilitative,' 'regulative,' and 'constitutive' legal environments, respectively.

Law as a 'Facilitative' Arena for Interaction

At its most passive, the legal system simply provides places, personnel, and procedures to accommodate organizational interactions that might otherwise occur elsewhere. The archetypal manifestation of this 'facilitative' aspect of law is the lawsuit: Organizations routinely employ litigation to open or defend markets, to attack or protect reputations, to reveal or conceal information, and so on. Courthouses are not the only relevant legal facilities, however; for example, organizations also use standard-setting bodies as vehicles for market dominance, patent filings as signals to potential investors, and Freedom of Information Act requests as instruments of corporate espionage. Across these and other contexts, the unifying theme of the facilitative legal environment is that, for better or worse, legal arenas offer congenial public venues for organizational activity, much as do public marketplaces and municipal convention centers.

As the preceding examples suggest, contemporary legal systems provide facilities for a wide array of organizational endeavors. To date, however, research on facilitative law has focused almost exclusively on one: law as an arena for disputing. Legal disputing takes place not only through traditional courtroom litigation, but also 'in the shadow of the law' (Mnookin and Kornhauser, 1979), through appended fora offering alternative dispute resolution (ADR) techniques such as mediation and arbitration (*see* Litigation; Mediation, Arbitration, and Alternative Dispute Resolution (ADR); Dispute Resolution in Economics). The best available evidence suggests that, in the United States at least, litigation against and among organizations has increased significantly since the early 1970s, at least in part because of a rise in the rate at which businesses sue one another (Dunworth and Rogers, 1996; Cheit and Gersen, 2000). Alongside this rise in interorganizational litigation, however, recent years have also brought increased use of ADR, which proponents claim can curtail the cost, delay, and adverse publicity of conventional adjudication (Lande, 2000). The resulting regime has been described as "process pluralism" (Bush, 1984), with an elevated level of overall disputing accompanying a reduced level of courtroom centrality.

Facilitative Law as Independent Variable

Although most studies of facilitative law portray organizations as the active players and the legal system as merely a passive arena, most also emphasize that the contours of this arena may determine the course of the game. In this sense, facilitative law tends to be depicted as an exogenous contextual variable in the disputing process (Hendley et al., 1999; Djankov et al., 2003; Ginsburg and Hoetker, 2006). Because much of this literature emerges from policy debates over litigation reform, investigation generally centers on whether particular procedural rules elicit or suppress lawsuits, and on whether changing rates of litigation exert positive or negative influences on nonlegal organizational activities (Dreyfuss, 1995; Choi et al., 2009). Standing-to-sue doctrines, class-action requirements, and contingency fee arrangements have all attracted attention as determinants of litigation behavior, and rising litigation has, in turn, received blame for a wide variety of adverse side effects, including increased insurance use, elevated bankruptcy rates, and a societal undersupply of high-risk innovation (Huber and Litan, 1991; Viscusi and Moore, 1993; Kagan, 2001). At the same time, a more upbeat literature on ADR asserts that the growing burdens of full-dress litigation have sparked managerial interest in nonjudicial alternatives, and that the resulting shift in dispute processing may have eased workplace tensions and strengthened ongoing business relations (Lande, 2000; Stipanowich, 2004). Other commentators, however, have noted that litigation may serve the salutary purpose of promoting corporate social responsibility, and that ADR, in contrast, may cool out genuine grievances and undercut public debate (Edwards, 1986; Edelman et al., 1993; Hensler, 2002).

Research on the link between forum structure and disputing behavior generally adopts a materialist orientation, examining how legal procedures affect the concrete costs and benefits of various organizational actions. If litigants enter court strategically, then the 'house rules' should determine both the attractiveness of the arena and the moves of the players. In addition to such obvious factors as expense, delay, and the magnitude of awards, litigation rates should be particularly sensitive to the predictability of trial outcomes, since if both sides have similar expectations about the results of a trial, rational parties will generally prefer to settle their disputes out of court (Priest and Klein, 1984). The most efficient judicial system, in this view, would be one in which the predictability of legal procedures encouraged disputants to resolve most matters through private negotiation, leaving the courts free to decide genuinely contested points of law with as little expense and delay as possible.

Recently, however, a number of culturalist researchers have borrowed from the literature on individual-level disputing to suggest that such rational-actor analyses may provide only a partial account, at best. Even among sophisticated business organizations, legal disagreements often involve substantial expressive and symbolic elements, and these cultural factors may play as great a role as rational profit maximization in determining organizational disputing behavior (Cheit, 1991; Lind et al., 1993). Thus, where materialists see litigation as 'economic competition by other means,' culturalists emphasize the relationship between law and 'softer' organizational phenomena such as alliance formation, community building, and reputation management (Blegvad, 1990). This perspective is particularly common in studies of ADR, which highlight the ability of dispute processing institutions to preserve or disrupt relationships, to harmonize or polarize viewpoints, and to privatize or publicize disagreements (Fuller et al., 2000; Hoffmann, 2005).

Facilitative Law as Dependent Variable

Alongside these analyses of how legal arenas shape organizational behavior, a handful of studies have reversed the causal arrow, to explore how organizational behavior shapes legal arenas. As the transaction cost tradition suggests, law is only one of many governance mechanisms, and if litigation arises in part from the failure of other controls, then extralegal organizational conditions may play a crucial role in shaping the work of the courts.

For the most part, the existing literature assumes that the relevant extralegal conditions are material rather than cultural, with factors such as economic globalization, industrial turbulence, and a shift from 'relational' to 'transactional' commerce topping the list (Cheit and Gersen, 2000; Kenworthy et al., 1996). Clearly, however, cultural conditions may also exert a significant influence. Preliminary findings suggest, for example, that professional ideologies strongly affect whether an organization's culture favors ADR or litigation; and organizational cultures, in turn, affect whether employees seek to resolve workplace grievances in-house or through the courts (Bies and Tyler, 1993; Fuller et al., 2000). Further, in a mirror image of Selznick's legalization dynamic, the spread of ADR techniques in the workplace tends to inject private organizational values into public legal discourses: Several major employment laws now explicitly encourage the use of ADR to resolve legal claims, and courts themselves increasingly employ 'appended' ADR to expedite settlement negotiations (Edelman et al., 2011; Hensler, 2002). Thus, the changes that began with rising litigation rates now appear to be coming full circle: Where organizations originally embraced ADR to escape the perils of formal legal arenas, the legal system is now

remodeling its own facilities to replicate these once-alien organizational proceedings. Even when legal institutions are at their most passive, the relationship between law and organizations proves to be both reciprocal and complex.

Law as a Code of Conduct

In addition to providing a procedural forum for organizational interaction, law can also act as a system of substantive edicts, imposing societal authority over various domains of organizational activity – from antitrust to labor relations to environmental protection (*see* Antitrust Policy: Lessons from the US Labor Unions). Formal regulatory oversight represents the archetypal manifestation of this 'regulative' aspect of law. But similar applications of sovereign authority can also occur through common-law precedents, street-level policing, and privately-enforced policy initiatives, such as tort claims against harassment, nuisance, or fraud. In all its guises, regulative law operates not merely as a neutral arena, but as a structure of precepts and enforcement mechanisms purporting to channel organizational behavior in particular directions. While regulative law may not always accomplish (or even sincerely intend to accomplish) its stated goals, the hallmarks of this aspect of the legal environment are a pervasive rhetoric of active social control and a pervasive concern with organizational compliance and evasion.

Regulation is almost certainly the most widely studied aspect of the relationship between organizations and the law. Unfortunately, most investigations to date have focused narrowly on particular substantive domains, and systematic efforts to explore underlying social processes remain relatively rare. Nonetheless, this literature displays a number of recurring themes. From a materialist perspective, regulative law serves to counterbalance market imperfections, imposing supplemental incentives and deterrents that recalibrate the implicit prices of various organizational behaviors. In this view, organizations respond to regulation by seeking to maximize total returns in light of the legal incentive structure, whether through petition and compliance or through manipulation and evasion. Alongside such economic dynamics, however, legal regulations also implicate deep-seated normative and cognitive beliefs (*see* Norms), and tactical maneuvers often cannot fully extricate organizations from these broader cultural processes: As statements of public values, laws shape and reflect what organizational stakeholders want, and as repositories of public meaning, laws frame and recapitulate what organizational stakeholders expect. Consequently, the underlying cultural logics of the organizational and legal realms often move in tandem, even as particularly recalcitrant firms may seek to amend or evade particularly burdensome strictures.

Regulative Law as Independent Variable

Tracing, first, the pathway from regulative edicts to organizational responses, research suggests that such legal pronouncements can operate both as material threats and as cultural sermons. As material threats, laws exert their greatest influence when standards are clear, sovereignty uncontested, and sanctions substantial (*see* Compliance and Legal Authority). In practice, however, such ideal conditions rarely pertain, and in their absence, self-interested organizations react not only to the incentives enunciated by law-on-the-books, but also to the gaps provided by law-in-action – ambiguous statutes, fragmented jurisdictions, manipulable enforcement agencies, and the like. These gaps, substantial in themselves, grow still wider in the face of organizational characteristics such as specialization and decentralization, which often marginalize legal voices and insulate managers from responsibility for corporate transgressions (Stone, 1975; Ashforth and Anand, 2003). As a result, the history of regulation is replete with unintended consequences: disclosure requirements that foster uninformative disclaimers (Samuels, 1996); tort liability that shifts hazardous activities into undercapitalized subsidiaries (Barney et al., 1992); air-quality standards that export pollutants to downwind communities (Ackerman, 1981). Although few researchers would rule out the possibility of successful deterrence, the common theme behind much of the materialist literature is that regulative law can easily mobilize evasion and resistance rather than obedience.

The pessimism of this literature stems in large part from the assumption that rational organizations lack the moral sentiments that promote individual-level respect for law (*see* Compliance and Legal Authority). Recent culturalist studies, however, call this assumption into question (Gunningham et al., 2005). Organizational behavior, after all, reflects the activities of culture-bearing individuals operating within decision structures that incorporate cultural values and cultural templates at every turn; it would be a bit odd, then, if organizational behavior responded only to law's material threats, while remaining impervious to law's cultural sermons (Howard-Grenville et al., 2008).

The leading attempt to examine regulative law through such a culturalist lens comes from 'neo-institutional' sociologists, working broadly in the Selznickian tradition. To these researchers, legal compliance simply represents a special case of 'institutional isomorphism' – the process by which organizations facing similar external rule systems become both increasingly alike and increasingly congruent with the myths of their shared environment (DiMaggio and Powell, 1983). In addition to applying material coercion, legal institutions also homogenize organizational behavior by shaping cultural beliefs: law enunciates normative values and ethics, which organizations then elaborate and internalize; and law provides cognitive models and scripts, which organizations then imitate and enact (Fuller et al., 2000; Stryker, 2003; Albiston, 2005). While the resulting isomorphism often amounts to little more than superficial ceremony, the neo-institutional perspective suggests that even 'empty' symbolism reenacts and thereby substantiates the law's cultural claims in ways that outright defiance would not.

Thus, investigations into the impact of regulative law on organizational activity suggest an ironic result: As a material deterrent, law is rarely sufficiently explicit, authoritative, and coercive to accomplish much beyond mere symbolism. As a cultural pronouncement, however, 'mere symbolism' can prove quite consequential – often extending a law's practical reach (for better or worse) well beyond the law's professed targets.

Regulative Law as Dependent Variable

Investigations into the reciprocal impact of organizational activity on regulative law reveal similarly complex patterns. At a

basic level, research confirms conventional wisdom: Organizations make substantial investments in electoral politics and backstage agenda-setting, and organizational actors occupy central positions on all sides of most policy networks (*see* Policy Networks). Contrary to many popular accounts, however, organizations often seem less interested in averting government 'interference' than in using regulation proactively to stabilize markets or manage competition (Fligstein, 1996). Legal incentives are easier to control than market prices, and as materialist accounts would predict, organizations invest heavily in securing this resource pool. These efforts extend well beyond formal lawmaking to encompass subsequent implementation activities as well. Legislative compromises can leave regulatory agencies with little substantive guidance and even less monetary support, and as a result, administrators often find themselves dependent on outside organizations for information, expertise, and even political cover (Baldwin and Cave, 1999; Pedriana and Stryker, 2004). Far from imposing top-down social control, the resulting process of regulatory capture – in which regulators become subservient to those they supposedly regulate – tends merely to institutionalize the indigenous practices of the regulated industry itself (*see* Regulation, Political Economy of).

Culturalist accounts supplement this Machiavellian power-dependence analysis in two ways. First, organizational participation in the lawmaking process may reflect ideological concerns, as well as material interests. Professional and social movement organizations, in particular, often blend moral entrepreneurship with institutional entrepreneurship, to align the regulative environment with their own ethics and worldviews (Hoffman, 1999; Greenwood et al., 2002; Dobbin, 2009; *see* Entrepreneurship and Organizations). Second, organizational and industrial culture may act as a 'filtering agent' between law-on-the-books and law-in-action (Kidder, 1983). Since popular understandings of legality come largely from mundane experiences in concrete settings, living law ultimately emerges not from legislatures or regulatory agencies but from real-world communities, where organizational beliefs and practices give form and content to otherwise vague legal principles. Indeed, many legal enactments are initially so ambiguous and contradictory as to do little more than signal that something in the regulative environment has changed – leaving the actual meaning of compliance to be constructed by subject organizations themselves, through an iterative process of interpretation, imitation, litigation, and reinterpretation (Edelman, 1992).

This culturalist perspective suggests a somewhat less sinister view of regulatory capture. Both regulator and regulated operate within the same institutional field, and shared exposure to a common set of filters and experiences can produce congruent outlooks even in the absence of *quid pro quo* power relations. Moreover, this dynamic can sometimes amplify, rather than dampen law's regulative impact: The literature reveals several instances in which savvy lobbyists, lawyers, and other professions have actually exaggerated legal demands in order to increase their own symbolic and practical importance – and have thereby constructed a regulatory environment that is more constraining than the original statutory framework may have envisioned (Edelman et al., 1992; Dobbin, 2009).

Law as a Typology of Experience

As well as providing an arena for interaction and a lever for social control, law can also enter organizational life more subtly, as a framework of categories and definitions that identifies the legally recognized components of the social world and that explains their natures and attributes. The archetype of this 'constitutive' aspect of law is the doctrine of corporate personhood, which defines particular social groups as unitary collective actors with coherent legal identities, interests, and capacities (*see* Multinational Corporations). Beyond incorporation, however, constitutive law also underpins virtually every other feature of the organizational world, from financial securities to intellectual property to employment relations (*see* Intellectual Property: Law in Context; Employment and Labor Regulation). Unlike facilitative and regulative law, constitutive law rarely attracts public attention, but its invisibility belies its agenda-setting power: By establishing fundamental background assumptions, legal definitions help to determine which types of organizations come into existence and which types of organizational activity come to be taken-for-granted. As a collection of basic templates and mechanisms, constitutive law often seems more placid and routine than its facilitative and regulative counterparts; in reality, though, this aspect of the legal environment provides the cognitive building blocks that underpin the other two.

Constitutive Law as Independent Variable

Because the materialist perspective emphasizes concrete conditions, it tends to downplay law's constitutive aspects: The physical realities of organizational life, one might argue, do not depend on the presence or absence of legal definitions – especially given that economic actors can usually specify, by mutual agreement, anything not already defined by law. Nonetheless, hints of a materialist approach to constitutive law appear, at least embryonically, in certain writings from the transaction cost school. Masten (1990), for example, suggests that the fundamental distinction between markets and hierarchies lies in the different 'default rules' that govern these two types of economic activity. Although a carefully crafted network of market contracts could theoretically achieve the same results as a corporate charter, the ready-made template of incorporation reduces the information and coordination costs of constructing such an architecture (Klausner, 1995). In a world of bounded rationality, many organizations would never come into existence without this handy shortcut. Law, then, can exert a substantial constitutive influence on organizational life simply by creating a basic tool kit of familiar categories and prebundled rights (Campbell and Lindberg, 1990).

Culturalist analyses go even further, seeing constitutive law not merely as a convenient starting point for strategic negotiation, but more fundamentally as a preconscious framework for making sense of the social world. In this view, law plays a central role in the "social construction of reality" (Berger and Luckmann, 1966), with legal definitions often becoming reified and institutionalized as taken-for-granted components of 'the way the world works' (*see* Law as Constitutive; Reification: History of the Concept). Culturalist researchers have explored such dynamics in several aspects of organizational life, including interorganizational relations, organizational structures, and the general cultural logic of 'legal rationality.' In the

constitution of interorganizational relations, contract law establishes rituals for forming binding commitments, property law determines the appropriability of resources and ideas, tort law assigns responsibility for social misfortunes, and so on (Suchman, 2003; Kapczynski, 2008; Clarke and Short, 1993; *see* Contracts: Legal Perspectives; Property: Legal Aspects; Torts in Law). In the constitution of organizational structures, law defines the characteristics of particular organizational features, such as affirmative action policies and 'poison pill' takeover defenses, and law also formulates the ground rules for entire organizational forms, such as private companies, public agencies, and nonprofit associations (Edelman, 1992; Dobbin et al., 1993; Davis, 1991; Salamon and Anheier, 1997). Finally, in the constitution of legal rationality, law generates sympathetic vibrations in other formalized and rationalized social structures, including organizational bureaucracies, drawing organizational embodiments of 'fairness,' 'citizenship,' and the like into synchrony with legal exemplars (Edelman, 1992; Sutton et al., 1994).

Constitutive Law as Dependent Variable

In depicting legal definitions as basic atoms of social structure, researchers from both the materialist and the culturalist camps tend to give short shrift to the study of constitutive law as a dependent variable. Nonetheless, legal categories, no matter how fundamental, are never facts of nature, and investigations into the relationship between organizations and the law have much to gain from examining how organizational activity may shape various constitutive constructs.

The existing literature offers several thought-provoking suggestions. First, in Gilson's (1984) memorable phrase, corporate lawyers may act as 'transaction cost engineers,' responding to unresolved governance challenges by recombining preexisting constitutive building blocks into novel configurations. Over time, the resulting 'legal devices' can serve as prototypes for increasingly routine reproductions – and the resulting standardized and typified artifacts can in turn provide the basis for revised legal categories (Powell, 1993; Suchman, 2003). Second, even without intentional innovation, organizations may inadvertently destabilize established legal definitions through imperfect implementation or awkward elaboration, generating legal pluralism and contradiction as an unintended consequence of everyday activity (cf Smets et al., 2012). Third, since legitimacy often stems from sheer numerical prevalence, organizations may skew the development of constitutive law simply by disproportionately employing some legal alternatives rather than others (Suchman, 2000; Edelman et al., 2011). Finally, as described above, organizations may participate directly in creating, interpreting, and implementing new legal categories and definitions, shaping the constitutive legal environment as advocates, as filtering agents, and as the concrete 'data points' that give substance to the law's abstract labels.

Future Directions

The study of organizations and the law has accomplished much in recent years; however, much still remains to be done. At a technical level, although both empirical and conceptual analyses abound, the former tend to focus on narrow policy concerns, while the latter tend to rest on meager evidentiary foundations. The challenge for future researchers will be to build firmer linkages between theory and data, and from those linkages, to develop a systematic body of intercomparable results. Cross-temporal and cross-cultural studies, in particular, seem essential to resolving the field's persistent debates over causal sequences and material/cultural mechanisms.

As such research takes shape, investigators are likely to encounter many phenomena that bridge the three major aspects of law and that comingle material and cultural processes. Ambiguous regulative statutes, for example, acquire meaning largely by motivating organizations to invent experimental legal devices that recombine old and new constitutive definitions in pursuit of plausible and advantageous models of 'compliance.' These recombination efforts inevitably generate test cases in facilitative legal arenas, which cases in turn further clarify and institutionalize the underlying constitutive definitions, the prevailing regulative standards, and the legitimate compliance options. In such dynamics, cultural and material considerations presumably overlap, since most laws set forth norms and penalties simultaneously and most legal devices blend technical efficacy and symbolic meaning. Indeed, under certain circumstances, the material/cultural distinction can virtually disappear, as when material punishment becomes a symbol of societal commitment, or when cultural legitimacy becomes an asset in market competition (Suchman, 1997).

In exploring such intersections, future research may accelerate a trend, already emerging among neo-institutionalists (e.g., Edelman et al., 2011), toward conceptualizing the relationship between organizations and law less as a matter of unilateral causation than as a matter of endogenous coevolution: Given the inherent ambiguity of law-on-the-books, the practical meaning of law-in-action develops only through a highly interactive process of social construction – involving both symbolic sense-making and concrete dealmaking. This 'structuration' dynamic (Barley and Tolbert, 1997) encompasses not only agents of the official legal system but also members of the focal organizational field, all tacitly collaborating to create simultaneously the forums and procedures of facilitative law, the demands and sanctions of regulative law, and the schemas and devices of constitutive law. Eventually this collaboration may produce a working agreement on what the law 'is' and on what it 'requires,' and that agreement may then become institutionalized in formal conventions and taken-for-granted beliefs. But saying that legal rules 'cause' organizational practices (or vice versa) would be a gross oversimplification. Rather, rules and practices arise in tandem, as part of the consolidation of a complexly intersectional organizational/legal field.

Organizations: Authority and Power

Cynthia Hardy, University of Melbourne, Parkville, VIC, Australia

Abstract

There are countless ways of defining power in organizations and explaining its relationship to authority. In this article, some of these differences are explored in terms of three broad perspectives found in the literature. First, *managerialist* perspectives differentiate legitimate, formal authority from illegitimate, informal power. Authority is assumed to be rational and functional; while power is typically seen as 'political' and dysfunctional. Second, *critical* approaches directly challenge managerialist approaches. They see organizations, not as rational, neutral, and objective, but as tools designed to fulfill the interests of one group at the expense of another. Power is hidden behind the mask of authority and embedded in the fabric of organizational life, operating to privilege employers over employees and managers over workers. Third, *discursive* views of power examine how communicative practices create organizational realities and identities that both constrain and enable individual action and thought. This article emphasizes the limits of trying to exercise power while, at the same time, helping us to understand how some actors are constructed as authoritative, albeit within the limits of the broader discursive context. Each approach is discussed in depth, and their assumptions and insights compared.

Managerialist Approaches: Power vs Authority

Managerialist research on power and authority is predicated on a rational orientation that seeks to make organizations more efficient and effective (or to understand why they are not). Authority is defined as the recognized, legitimate right to make a decision. In contrast, power is typically employed by those who oppose management, resist change, or pursue self-interest – those who seek to subvert the 'legitimate' power embodied in the organizational hierarchy (see Thomas and Hardy, 2011). Even when these researchers acknowledge that managers do use power, as opposed to authority, they suggest that it is only in self-defense – to pursue organizational goals in the face of resistance. Since authority is considered a 'normal' and 'inevitable' phenomenon that results from the formal design of the organization, it is largely excluded from analysis as research concentrates on power that is exercised outside formal hierarchical structures. Accordingly, managerialist work on power stems from an interest in why and how decisions, which 'ought' to be rational, instead become political as groups use their power to influence decision outcomes in their favor.

The managerialist approach to power in organization and management theory (OMT) is similar in its underlying assumptions to the early studies of community power carried out by American political scientists. In this section, an overview of this article is provided, followed by a discussion of the OMT literature in more detail.

Community Studies of Power

Some of the most influential early work on power was conducted, not in management, but in community studies conducted by political scientists. These researchers (e.g., Dahl, 1957) analyzed the decision-making process in American towns and communities to explore the prevailing power relations. The object was to determine who made these decisions: if the same groups were responsible, the community could be said to be ruled by an élite group as had been proposed by sociologists like C. Wright Mills (1956). If, on the other hand, a variety of groups had an impact on decision outcomes, the community could be described as pluralist. Dahl and other researchers found evidence of the latter, and hypothesized that America as a whole was a pluralist society insofar as, rather than being dominated by a small number of élites, it was populated by diverse groups with equal opportunities to exercise power and influence decisions.

Several assumptions underlay this research. First, researchers assumed that individuals were aware of any grievances they had regarding the political system and, further, they acted upon them by participating in decision making and attempting to influence key decisions. Second, the decision-making arena was open to anyone with a grievance and, therefore, if individuals did not participate, it indicated that they agreed with decision outcomes and the political system more broadly. Third, power was exercised only in decisions where conflict was clearly observable: if conflict was not observed, it was because consensus prevailed. Moreover, such conflict was resolved primarily through political decision-making arenas (see Lukes, 1974).

Lukes (1974) referred to such views of power as 'one dimensional'. He goes on to identify a second dimension of power that emerged as researchers challenged these assumptions. Specifically, Bachrach and Baratz (1962) questioned whether decision-making processes were open to everyone. They argued that nonparticipation did not necessarily reflect genuine satisfaction but, instead, meant that individuals were unable to secure access to decision-making processes. Researchers began to focus on how participation in decision making was constrained – by excluding individuals from the decision-making arena or limiting the participation of those who did secure access to it. Bachrach and Baratz (1962) showed how dominant actors were able to confine the agenda to 'safe' questions and the arena to 'safe' participants, while more difficult matters were dealt with outside formal decision making. They called this process 'nondecision making' because it allowed the more powerful actors to determine outcomes from behind the scenes.

The work on nondecision making broadened the research agenda, but it continued to operate on similar assumptions as the one-dimensional view of power. Specifically, it assumed that some form of conflict was necessary for power to be exercised, i.e., groups had to have some form of grievance, and desire different decision outcomes if their political opponents were to initiate nondecision making to try and ensure that this did not happen (Lukes, 1974). Thus, from a theoretical perspective, the first- and second-dimensional views of power converge: both focus on the exercise of power in or around the decision-making arena as part of a deliberate strategy to achieve intended outcomes in the face of conflict. Power mobilized through nondecision making may be less visible than decision-making power – since opponents may be sidelined rather than directly confronted – but it is still premised on the existence of conflict and opposition (Hardy, 1985).

Managerialist Studies of Power in OMT

Although conducted separately and with a different rationale, managerialist studies of power in OMT adopted a similar view of power as the literature described above insofar as researchers explored how individuals in organizations exercised power as part of a deliberate strategy to achieve intended outcomes in the face of opposition. In particular, researchers focused on uncovering the sources of power that allowed actors who did not possess legitimate authority to influence decision outcomes. In this way, researchers began to differentiate between formal, legitimate power – authority – and informal, illegitimate power.

Crozier (1964) studied how maintenance workers in a French state-owned tobacco monopoly had a high degree of power in relation to their position in the hierarchy because they controlled the uncertainty associated with breakdowns of equipment. This and similar work contributed to the strategic contingencies theory of intraorganizational power (Hickson et al., 1971), which argued that subunits within an organization were powerful when they were able to cope with greater amounts of uncertainty, were central, and were not easily substitutable – in other words, when other subunits depended upon them. Similar assumptions underpinned the resource dependency view of power.

> This theory states that power resides among a set of interdependent subunits or organizations that exchange resources with each other. The value of the resources that a subunit/organization controls and the extent to which those resources can be obtained elsewhere (i.e., the subunit/organization's substitutability in the exchange relationship) determine the terms of exchange, and thus the power in relation to other subunits/organizations. If the value that a subunit/organization provides can be replaced (i.e., substituted), then there is little dependence on that subunit/organization, which consequently has little power in that social relationship.
> (Magee et al., 2008: p. 362)

Researchers began to identify the resources that constituted the bases or sources of power, such as information, expertise, credibility, prestige, access to higher echelon members, and the control of money, rewards, and sanctions (Pettigrew, 1973). They also questioned whether simply possessing scarce resources was enough to confer power, arguing that actors also had to be aware of their contextual pertinence and sufficiently skilled to deploy them. This process of mobilizing power was typically referred to as 'politics', which further reinforced the idea that the use of power was illegitimate, dysfunctional, and self-serving.

Researchers using this approach to power, concentrated on the link between power and the control of scarce resources – or dependencies – that helps actors to influence decision-making processes in the face of opposition. Those individuals with the greatest access to power sources and the greatest skill in putting them to use are the most likely to prevail in decision making. Decision outcomes produced in this way are described as political, rather than rational, and are typically assumed to be at odds with the interests and objectives of those in formal authority. Power is only used in the first place because of the existence of conflict.

> [It] is clear that political activity is activity which is undertaken to overcome some resistance or opposition. Without opposition or contest within the organization, there is neither the need nor the expectation that one would observe political activity.
> (Pfeffer, 1981: p. 7)

In this way, the use of power is inextricably linked to the situations of overt conflict associated with struggles among actors seeking to protect vested interests.

This managerialist work on power thus converges theoretically with the study of community power. First, both community and OMT researchers challenged the existing models of decision making. Studies of community power refuted the élitist views of decision making suggested by some sociologists to propose a pluralist perspective; while management studies of power challenged the existence of the rational model in organizations by saying that decision making was, in fact, political (although, whereas political scientists tended to promote pluralism – and the attendant politics – over élitism, management researchers clung to rationality as the desirable mode of functioning). Second, both bodies of literature adopted a behavioral approach that focused on the overt exercise of power in the decision-making arena, and both argued that decision outcomes were influenced by actors' access to and expertise in using power (although OMT researchers seemed uninterested in the concept of nondecision making, which did not gain much traction in this literature). Third, both bodies of work employed similar definitions of power, i.e., the ability to get others to do what you want them to, if necessary against their will (Weber, 1947) or to do something they otherwise would not do (Dahl, 1957).

While managerialist approaches in OMT have produced insight into some aspects of power, existing organizational arrangements – particularly in the guise of legitimate authority – are largely excluded from analysis. Power represents dysfunctional interruptions in the far more desirable flow of rational decisions by self-interested actors who engage in its political mobilization, a term whose negative connotations helped to reinforce the view that power is illegitimate and dysfunctional (except, perhaps, when used by managers in defense of organizational goals). As power and authority were pulled further apart, authority was increasingly taken for

granted; with researchers rarely stopping to consider how it got there or whose interests it serves. Power was what counted – and what fascinated – researchers (Hardy and Clegg, 2013).

> Power, related to one's control over valued resources, transforms individual psychology such that the powerful think and act in ways that lead to the retention and acquisition of power.
> (Magee et al., 2008: p. 351)

As the managerialist literature has grown, it has increasingly conceptualized power in highly individualized terms: as individual control over valued resources that are asymmetrically distributed in social relations. Confidence in the predictive ability of power mechanisms such as hierarchical position, perceptions of competence, self-enhancement, hedonic sense-making, and the desire to win has led researchers like Jeffrey Pfeffer (2013) to claim their universality as determinants of organizational outcomes.

> Not only does power induce different motivations in individuals, but the powerful soon learn that they can get away with things that others cannot.
> (Pfeffer, 2013: p. 277)

In contrast, Willmott (2013a: p. 281) argues, "power and influence reach well beyond the surface mechanisms identified and naturalized by Professor Pfeffer." He argues that managerialist work ignores and obscures the ways in which power is institutionalized and reproduced – to the extent that this approach can be said to constitute *uncritical* management studies.

> [Power] tends to be conceived shallowly as an attribute of individuals and groups who possess it, and to be manifest in zero-sum games involving acquisition, exercise, and potential loss of power [which] reflects and reinforces a highly individualized and individualizing representation of an episodic manifestation of power that largely displaces consideration of its relational formation and systemic operation.
> (Willmott, 2013a: p. 285)

So, let us now turn to *critical* management studies to see how work in this area has treated power and authority.

Critical Approaches: Power, Authority, and Domination

Research in critical management studies, a term used here to refer to a diverse body of research (see Willmott, 2013b), adopts a very different approach to power and authority than the work described above. Critical management researchers argue that power is embedded in formal organizational structures and that decision-making processes, which may appear to be neutral, rational, or logical are, in fact, designed to serve managerial interests. Hence, hierarchy is not authority, but power and domination; while actions taken to challenge it constitute resistance to domination, rather than the illegitimate use of power. Critical management researchers examine how power is embedded in societal and organizational structures, ideologies, and narratives. They assert that much of what appears to be apolitical is, in fact, both a product and a medium of power. This view has helped to expose how power, concealed in the legitimate trappings of structures, rules, class mechanisms, and cultures, produces quiescence and prevents conflict from arising. In the following section, Lukes' (1974) third dimension of power is examined and the adoption of a similar radical or critical view in OMT is explored.

The Third Dimension of Power

Having identified the first and second dimensions of power described above, Lukes (1974: p. 24) presented a third dimension of power. He argued that power can be used to shape perceptions, cognitions, and preferences to the extent that individuals "accept their role in the existing order of things, either because they can see or imagine no alternative to it, or because they view it as natural and unchangeable, or because they value it as divinely ordained and beneficial." Consequently, the study of power cannot be confined to observable conflict, the outcomes of decisions, or even suppressed issues. It must also consider the question of political *quiescence*: why grievances do not exist; why demands are not made; and why conflict does not arise in situations of inequality? In other words, researchers were interested in how power is used to maintain the dominance of élite groups by reducing the inclination of subordinates to employ their discretionary power.

Lukes' interest in the societal and class mechanisms, which perpetuate the status quo, relates to the ability of dominant classes to define reality to support and justify their material domination, thus preventing challenges to their position, and avoiding the necessity of using more coercive, visible forms of power. According to this view, stable organizing power is based on the third dimension – the ability to avoid conflict and opposition by making power appear legitimate, thereby rendering its use by dominant actors less visible.

Critical Views in OMT

The fact that organizations tend to serve managerial interests had not been lost on all organizational researchers. Nor had the political advantages of legitimacy gone completely unnoticed as Pettigrew (1979) showed how interest groups legitimized their demands to prevent conflict through symbolic activity. Critical management researchers went further to examine the way in which power is embedded at a 'deeper' level in organizational structures, cultures, and ideologies, and as political actors try to section off spheres of influence where domination is perceived as legitimate and thus unchallenged (e.g., Clegg, 1975). This use of power is largely invisible and designed to avoid conflict altogether rather than trying defeat it once it has arisen (Hardy, 1985).

Another critical perspective on power was provided by labor process theorists (e.g., Burawoy, 1979) who focused on the dynamics of power and resistance in relation to phenomena such as gender, technology, ethnicity, managerial work, and other aspects of the structuration of work and its organizational context. More recently, such work has critically examined the empowerment and teamwork practices that characterize

contemporary management practice. Far from providing employees with more power, researchers argue that these practices embody subtle, invisible controls. The terminology of empowerment helps to avoid conflict and resistance by emphasizing consensus and cooperation, while managerial control is reinforced through the language of the team effort and peer pressure. A critical perspective thus sees empowerment as an exercise in the management of meaning, designed to enhance the legitimacy of organizational goals and to influence behavior unobtrusively.

In summary, critical approaches to power are substantively different in their assumptions compared to managerialist views of power. Power is domination; authority is one form of domination; and resistance is a repudiation of that domination. Power and resistance are differentiated in order to indicate "qualitatively different contributions to the outcome of power relations made by those who exercise power over others, on the one hand, and those subject to that power, on the other" (Barbalet, 1985: p. 545). According to this approach, power is used not simply to defeat conflict, but to prevent it from arising in the first place. Critical management research focuses on this subtle, repressive use of power, attempting to reveal the hidden aspects of domination, helping to facilitate resistance, and enabling groups to free themselves from the effects of power.

Discursive Power: Reconstructing Authority

Critical research has itself come in for criticism, particularly for the idea that revealing and resisting the hidden way in which power is embedded in the fabric of organizations can produce a situation 'free' of power, and that critical theorists have a privileged access to reality that permits them to stand outside the power relations that they are exploring. As a result, many researchers – including many already inside the critical camp – turned to the work of poststructuralist researchers to adopt a discursive view of power. In this section, work that links power to discourse is explored, particularly the work of Michel Foucault (e.g., 1980).

Foucault: The End of Authority?

The work of Foucault challenges the very idea of authority by downplaying the relevance of 'sovereign' power in contemporary society. Gone is the idea of a supreme authority that determines organizational outcomes. Power is no longer a convenient, manageable resource controlled by autonomous individuals, whether by exploiting or circumventing hierarchy. Instead, a network of power relations – or discourses – captures the advantaged and disadvantaged alike.

> [I]n any society there are manifold relations of power which permeate, characterize and constitute the social body, and these relations of power cannot themselves be established, consolidated nor implemented without the production, accumulation, circulation and functioning of a discourse.
> (Foucault, 1980: p. 93)

Discourses are collections of interrelated texts and practices that "systematically form the object of which they speak" (Foucault, 1972: p. 49). They produce particular meanings, as a result of which particular kinds of objects and subjects become 'known', through which and upon which particular relations of power are realized. In influencing the way in which a topic or issue can be talked about – or acted upon – power circulates through discourse, constraining and enabling what individuals can think, say, and do.

Actors may try to manipulate resources, structures, or meanings with the intention of achieving particular outcomes but, according to Foucault, no matter how hard they pull on the 'strings' of power, they are unlikely to attain their desired ends.

> People know what they do; they frequently know why they do what they do; but what they don't know is what what they do does.
> (Foucault quoted in Dreyfus and Rabinow, 1982: p. 187)

These limits to power and authority can be found in the complexity of power relations: the way in which they are productive, and not only repressive; their link to knowledge; and their pervasiveness.

This network of power produces the subject (Knights and Morgan, 1991). According to this view, the individual is not a stable constellation of essential characteristics, but is associated with multiple, socially constituted categories. Identities are salient only insofar as they are socially recognized. Thus the subject is not a 'given' but produced historically through power–knowledge relations. This effect of power is not necessarily alienating or repressive. It is also productive and positive insofar as it transforms individuals "into subjects who secure their sense of what it is to be worthy and competent human beings" (Knights and Morgan, 1991: p. 269). Foucault also challenges the idea that one can escape the regimes of power through knowledge, arguing that knowledge can never be separated from the effects of power. Knowledge does not strip away the effects of power to reveal the 'truth'; all it accomplishes is the embodiment of new and different forms and relations of power. What is accepted as 'true' are those mechanisms that "enable one to distinguish true and false statements … the techniques and procedures accorded value in the acquisition of truth; [and] the status of those who are charged with saying what counts as true" (Foucault, 1980: p. 131). Finally, the embedding of power relations in every aspect of one's life – including identity – makes them difficult to repudiate. They are experienced as reality, making alternatives difficult to conceive of, let alone enact. Resistance can usually only be conceived of in terms of the prevailing power relations and is subsequently at a risk of being 'colonized' by them; it is as likely to reinforce existing power relations as to overthrow them (Clegg, 1989). In this way, the emancipation for which critical approaches strive becomes illusory: power relations may change as a result of resistance but they do not disappear.

Foucault's work thus posits a very different conceptualization of power to both managerialist and critical views. Not only is there no autonomous subject waiting – or even willing – to be liberated through critical awareness, it is also erroneous to assume that emancipation can be achieved by the knowledge gained through critical reflection. Even if resistance is

successful, the resulting situation can never be free of power – it simply represents a *different* power regime. Moreover, these power relations affect all actors – capital and labor, employers and employees, researchers and research subjects. No one has the privilege of standing outside power.

> Power must be analyzed as something which circulates, or rather something which only functions in the form of a chain. It is never localized here or there, never in anybody's hands, never appropriated as a commodity or piece of wealth. Power is employed and exercised through a net-like organization…[Individuals] are always in the position of simultaneously undergoing and exercising this power.
> (Foucault, 1980: p. 98)

This power is impossible to escape. It encompasses, surrounds, and infiltrates in ways of which individuals are often unaware. It is productive yet constraining; it makes them what they are and, yet, makes it difficult to become anything else: authority becomes an illusion and politics, an indeterminate enterprise.

Organizational Discourse: Reconstructing Authority

Foucault's work focuses attention on how the institutionalization of practices and structures embody sets of power relations that are deeply embedded in the taken-for-granted rules and practices that constrain action (Clegg, 1989). In linking power and discourse, he shows how actors are locked into positions by way of the linguistic practices available to them to make sense of a situation. This form of power lies neither in the possession of individuals nor in the dependency relationships among them. It is embedded in the fabric of organizational life, reproduced by the day-to-day communicative practices and struggles of its members. Organizational reality is characterized less by the domination of one group over another, but by complex discursive practices that "define what it means to be an organizational member and … allow for the privileging of managerial interests over others" (Deetz and Mumby, 1990: pp. 32, 39).

Some writers have criticized Foucault for a supposedly agentless and overly pessimistic conceptualization of power, partly stemming from the belief that in linking power to discourse, Foucault was reducing it to language. However, as Foucault (1980: p. 57) himself has pointed out, discourse is not composed only of linguistic components, it is also embedded in material practices: "nothing is more material, physical, corporeal than the exercise of power." Accordingly, his work allows researchers to ask more far-reaching questions about power (Hardy and Thomas, 2014). Rather than simply asking who has power, researchers can ask how does power circulate through discourse, with a view to problematizing its institutionalization and reproduction as well as identifying its limits. Rather than seeing resistance only as an adversarial response to authority, researchers can ask how power and resistance operate together as part of the complex web of relations linking actors in everyday organizational life. Rather than asking how is power exercised repressively 'over' others, researchers can ask what does power produce and how does it shape our everyday life.

> [Power] produces reality; it produces domains of objects and rituals of truth. The individual and the knowledge that may be gained of him belong to this production.
> (Foucault, 1979: p. 194)

In this way, researchers can focus on how a particular discourse positions actors: which actors secure rights to speak, and which actors do not. They can examine the way in which actors draw upon discourses, and the language, genres, and linguistic strategies they use. They can explore the meaning attached to different categories of object in the discourse, the procedures, and practices that are invoked, and the way in which particular actors stand to gain or lose from the deployment of discourse. This article, implicitly or explicitly, resurrects the notion of authority by acknowledging that certain actors and institutions are constructed as authorities and authoritative.

Conclusions

This article has examined a number of approaches and explored their insights into the relationship between power and authority. Managerialist views of power differentiate legitimate, formal authority from illegitimate, informal power. The former is assumed to be rational and functional, the latter is typically seen as political and dysfunctional. This view of power is not contained within a particular body of literature on power; rather it permeates much of the mainstream work in OMT that sees organizations as rational decision-making systems, albeit flawed ones. Critical approaches directly challenge this managerialist work. They see organizations, not as rational, neutral, and objective but as managerial tools designed to fulfill the interests of one group at the expense of another. Power is embedded in the fabric of organizational life, hidden behind the mask of authority, and designed for domination. Discursive views of power wrestle with the notion of authority. They dispel the idea that either authority or power can be a pliable means of domination but, at the same time, show how authority emerges from contested, productive, and transgressive power–knowledge relations.

Organizations: Negotiated Orders

Tony J Watson, University of Nottingham, Nottingham, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The negotiated order of an organization is the pattern of activities that has emerged over time as an outcome of the interplay of the variety of interests, understandings, reactions, and initiatives of the individuals and groups involved in the organization. To examine negotiated orders in any given organization is to turn away from the more traditional way of looking at organizations that give primacy of attention to the pattern or ordering of activities chosen (or 'designed') by those officially in charge of the organization. The concept started its life in the study of the hospital and was originally used within a broadly interactionist frame of reference. However, it has close affinities with a series of other developments in organization theory, and it provides a way of dealing with the issues that were once considered in terms of the theoretically inadequate distinction between formal and informal organizations. This is especially the case if the distinction between official and unofficial aspects of organizing is incorporated into a negotiated order perspective. More and more, the negotiated order notion is being linked to that of the social institution, and this makes it an invaluable conceptual resource for the type of multilevel analysis to which researchers are increasingly turning.

Origins of the Concept in a Hospital Study

The concept of 'negotiated order' first appeared in a study of a psychiatric hospital (Strauss et al., 1963). The study focuses on the interactions of the variety of individuals and groups who are involved in its activities. These include the doctors, nurses, patients, patients' families, social workers, nutritionists, administrative workers, and so on. Although the rules, policies, official procedures, and hierarchical statuses of the hospital play a part in the patterns that emerge from the interactions that take place, the patterns are shown to be emergent. They emerge from the processes whereby different parties make use of rules, procedures, and information and negotiate between them what actually happens. These negotiations are characterized in a variety of ways, such as agreements, contracts, understandings, pacts, and so on. But two things are emphasized throughout. First, it is stressed that these negotiated outcomes are always temporary and have to be made and remade over time. A head nurse, for example, may gain agreement to move a patient to another ward, after it is agreed that the first ward has 'tried for a little longer' with that patient. In the light of how that patient fares, however, the patient may or may not subsequently be moved. The 'deal' will have been remade, implicitly or explicitly. Second, it is stressed that there is a patterning to what might, at first sight, appear to be a series of unique encounters. The deal between the head nurse and the doctor over a particular patient in specific circumstances, for example, takes place in the light of how interactions between members of these two occupational groups generally occur across the hospital.

Out of the ongoing multiplicity of interactions and negotiations, a pattern of hospital life, a negotiated order, emerges. Order is thus not imposed on social actors by the hospital but the 'order,' which, in effect, is the hospital is socially constructed by the interactions of the various individuals and groups. And each of these brings to the negotiation of order their own interests, understandings, loyalties, knowledge, occupational standing, and social origins. All these elements themselves are liable to change as they are taken into processes of reality negotiation.

Negotiated Order: Processes, Rules, and Rules

When Strauss et al. introduced the concept of negotiated order in their hospital study, they did not claim a generalized relevance for the concept. However, the leading researcher, Strauss (1978), later showed how it could be used more generally to understand organizational processes, including ones in industrial organizations. Its insights have subsequently been incorporated into a broad stream of thinking about organizations that focuses on *processual* aspects of organizational life. The approach emerged from the symbolic interactionist tradition of social psychology, a perspective that stresses the two-way relationship between human beings and their social context. People construct their realities through processes of interaction with others, and their identities emerge as part of this process of interacting and reality making. Such a theoretical approach, with its strongly antideterminist orientation, inevitably leads to a questioning of views of organizations that treat the formal arrangement of roles, rules, and procedures as the major determinants of the activities of organization participants. Indeed, Strauss et al. explicitly identify their study with such a critical stance on orthodoxy: "Students of formal organization tend to underplay the processes of internal change as well as overestimate the more stable features of organizations – including its rules and its hierarchical statuses" (1963, p. 147).

The emphasis of the Strauss et al. study on interactive and processual aspects of organizations was not peculiar to this group of social scientists and their study of a mental hospital. In particular, Goffman's similarly interactionist classic study, *Asylums* (1961), has clear parallels with the Strauss et al. study (which was partly influenced by early accounts of Goffman's research). And the same argument can be made with regard to Dalton's participant observation study of managerial work in an industrial setting. In fact, it was this study that Strauss (1978) used to illustrate the position he later came to take: that the negotiated order concept had a wider currency than had earlier been implied. He notes that Dalton's detailing of what Strauss calls "sub-processes of negotiation" is especially rich. Many researchers in managerial behavior would probably agree that few studies have surpassed Dalton's analysis of how

managers engage in; as Strauss puts it, "trading off, the paying off of accumulated obligations, the covert making of deals and other kinds of secret bargains, the use of additional covering negotiations for keeping hidden the results of previous covert arrangements, the bypassing of negotiations, and the mediating of negotiations; also, a very complex balancing of accumulated favors and obligations, along with the juggling of commitments within the negotiations itself" (1978, p. 139).

One particular area where Strauss et al. (1963) follow Dalton (1959) is in attending to the frequency with which formal rules are broken, stretched, or ignored, not only to suit sectional purposes but also to 'get things done.' A similar insight is central to ethnomethodological writing on organizations. This contributes to an understanding of how 'orders' are produced in organizations by focusing closely on how individuals, in their organizational interactions, 'work,' especially through talk, to present what they are doing as 'sensible' because it accords with rules (Bittner, 1965; Silverman and Jones, 1976). The rule (or even the organization itself) is not something preexisting or existing outside ongoing organizational interactions. It is, rather, a resource that people draw upon to legitimize their actions and further whatever projects they are pursuing in the work context.

This perspective, combining ethnomethodological insights with the notion of negotiated order, can be illustrated with a small case study. A van driver was overheard explaining to a factory security officer who had stopped him why he and his colleagues regularly took an illegal shortcut across a large industrial plant. He said, "The company says that all employees should use their initiative, always thinking of the customer first. By driving this way we are getting the goods out to the customer as quickly as we can. The other security men know this, and don't stop us." Ethnomethodological analysis would point to the way this driver uses a notion of the organization (the company) as one resource and utilizes a rule (use initiative and put customers first) as another. This is the negotiating of order in practice. Unofficial negotiations between van drivers and security officers that allowed driving along an illegal route through the plant to become part of the order of the organization had occurred. It suited both parties (a quiet life for the security people and a saving of time and effort for the drivers), and it got the job done. However, we must remember that negotiated order thinking sees such deals as continually liable to change. In fact, such a change was happening on the day these events were observed. A new security man had started work. And he believed that the one-way rule (which made the short-cut illegal) was necessary for protecting the safety of employees working in the plant. He, too, utilized a notion of 'the organization' and drew on a rule when he said, "You should realize that the company puts employee safety before even customers. Don't drive down here again." He got his way – for the time being.

Ambiguity, Interpretation, and Enactment

It might be argued that the above case is not looking at rules in a proper sense and that the individuals in the case study were talking simply in terms of inferred rules. But organizational thinking that follows a broad negotiated order approach would accept that all rules, or any other organizational procedure for that matter, are ambiguous. An important work in this tradition by March and Olsen (1976) argues that all organizational choices occur in a context where there is ambiguity about everything, from organizational goals and rules, through to the technologies used and people's knowledge of the past. Weick (1979), in another important contribution to this broad style of thinking, similarly points to equivocality in every aspect of the work of organizing. Members of organizations create the organization (or, rather, achieve organizing) through continuous processes of interpretation and action based on interpretations: They enact both the organization and the environment to which it relates.

Out of a range of partly linked theoretical origins – symbolic interactionism, phenomenology, and Weberian interpretative sociology – a general style of organizational analysis has developed which, in one way or another, incorporates the negotiated order insight. It is a processual style of analysis. It treats organizational patterns as emergent rather than as the creations of their managerial designers. And such an emphasis has been reinforced by the influence on organization theorizing of postmodern thinkers. Chia, for example, adopting an 'ontology of becoming,' encourages the analysis of the "discursive micro-practices which generate [the] stabilized effects" which constitute 'organizing' (Chia, 1996, p. 149).

The Negotiation of Order: Building upon and Going beyond the Classic Formal/Informal Organization Distinction

The concept of negotiated order provides a valuable analytical handle for dealing with the interactive and processual aspects of organizations, and one of the most important ways in which the broad idea of organizations as negotiated orders has influenced the study of organizations has been in its displacing of a powerful earlier distinction between formal and informal organization. This distinction was once widely used in organization theory, industrial sociology, and managerial writing to draw attention to aspects of patterned activity in work organizations that are not part of the formally or officially designed rules, relationships, and procedures that constitute the formal dimension of the organization. Informal organization is seen variously as something that works, or might be made to work, in conjunction with the formal organization, something that can exist with a degree of independence from it or something that can work against the formal aspects of the organization – especially when it takes the form of deviant behavior that resists or defies managerial authority. The formal part of an organization was identified in *Management and the Worker* (1939), a book that is famous as the key account by Roethlisberger and Dickson of studies carried out by academics from Harvard University and members of the Western Electrical Company at that company's Hawthorne plant. 'In short,' say Roethlisberger and Dickson, "the patterns of human interactions, as defined by the systems, rules, policies, and regulations of the company, constitute the formal organization." It is commonly assumed that the "organization of a company corresponds to a blueprint plan or organization chart" (Roethlisberger and Dickson, 1939, p. 559). 'Actually,' they say, "it never does." The study revealed

what Roethlisberger later referred to as "the emergent patterns of behavior that evolved within this formal organization" (Roethlisberger, 1968, p. 262). This informal organization was made up of "the practices, values, norms, beliefs, unofficial rules, as well as the complex network of social relations, membership patterns and centers of influence and communication that developed within and between the constituent groups of the organization under the formal arrangements but that were not specified by them" (Roethlisberger, 1968, p. 262).

These insights from the Harvard-based factory studies were taken up and developed at the managerial level of organization by Barnard in another classic Harvard study *The Function of the Executive* (1938). Barnard noted the paradox that, although executives tend to speak of their work primarily with reference to the "formal scheme of work tasks – and, indeed, deny the importance of the informal side – they nevertheless intuitively recognize its vital significance." "Learning the organizational ropes" in most organizations, he points out, "is chiefly learning who's who, what's what, why's why, of its informal society" (Barnard, 1938, p. 121). Consequently, it is on this aspect of the organization that executives need to focus their attention.

It is impossible to overestimate the importance of these insights into the development of organization and management studies, and it is clear that the empirical knowledge produced by these enormously important writers is vital to any consideration of the negotiation of order in organizations. Also, as ethnographic and, especially, participant observation studies of organizational activities began to appear, the more attention was drawn to facets of organization life that could not be accounted for in terms of formal administrative systems. Roy's (1960) participation observation of shopfloor work drew attention to how his colleagues used games and rituals to shape their day and overcome the monotony that the straightforward compliance with formal procedures would create. And later research by Burawoy (1979) in the same plant showed how workplace practices which might, at first sight, seem to challenge the dominant interests that the formal arrangements of the factory were designed to serve, in practice accommodated workers into the dominant patterns of interest. At the managerial level, Dalton's (1959) participative observation study showed the considerable extent to which senior organizational members organized themselves and behaved in ways that would be quite unexpected from a reading of their formal roles and duties. And Mangham and Pye's (1991) interview-based study of senior executives shows how close much of the thinking of these individuals was to Barnard's conception of the executive role and its focus on informal activities. This includes their relationships with other senior managers: "Many stressed that informal organizing, the structuring of the top team, was as important as, if not more than, the articulation of a formal organization" (1991, p. 8).

Given all of this, one is bound to ask why so little use is made of the formal/informal distinction in contemporary literature. This question can be answered by pointing to the movement in organization theory away from systems thinking and toward more processual thinking, the spirit of which is better captured by the idea of the negotiation of order than by the notion of there existing formal and informal elements of organizational systems. Roethlisberger was explicit, for example, in saying that the "notion of a natural social system" should be understood as 'underlying' the way of thinking which distinguishes between formal and informal organization (Roethlisberger, 1968, p. 261). And theorists, in part influenced by the way in which ethnographic work has tended to demonstrate the greater emphasize on matters of process rather than the existence of systems, have increasingly found this notion unhelpful. Further, systems thinking is seen as representing work enterprises in too unitary a manner, as failing to recognize the multiplicity of meanings and interests existing within the organization and as underplaying the relationships between organizations and wider societal patterns and processes. It can also be argued that with the managers of organizations now setting out to manipulate corporate cultures, publish mission statements, facilitate team working, and empower workers, there is such a blurring of the formal and the formal aspects of managerial initiative that the distinction is difficult to use when setting out to analyze the organizations in which this occurs. Managers have incorporated into the formal aspect of their organizations' activities that were once regarded as informal. An alternative distinction to the formal/informal organization one is that between official and unofficial aspects of organizations. This pair of concepts enables fully processual and negotiation-of-order analyses to be made as the researcher examines the interplay between "the managerial aspirations expressed in official management statements, policies, and claims and the observable patterns of belief and behavior that prevail across organizations in practice" (Watson, 2012, p. 119).

The Continuing and Future Power of the Negotiation of Order Perspective

The original way in which the negotiated order concept was used was criticized, even by broadly sympathetic critics like Day and Day (1977), for insufficiently grounding its analysis of interactional processes in their wider political, structural, and historical context. Strauss's later work responded positively to some of these points and, in particular, demonstrated how the approach could handle such allegedly neglected matters as conflicts that are "endemic, or essential to relations between or among negotiating parties" (1978,p. 290). Although, as has been demonstrated above, the negotiated order insight runs through a great deal of organization analysis, its terminology has not been used in an explicit manner as widely as might be expected. This may reflect reservations about the extent to which the analysis of negotiated orders within organizations can add to organizational theorizing generally if it focuses primarily on interactional patterns within those organizations. Perhaps the perspective, at least its explicit adoption, has had less impact than it deserves because it has been deemed inadequate as a general perspective for the study of organizations and their management. This problem can be overcome if the significant insights that it offers are incorporated into broader perspectives that link activities at the intraorganizational interactional level to wider societal patterns and processes.

Harking back to the origins of the negotiated order concept in the study of health provision, Sambrook (2001) examines the emergent patterns of human resource development in the British National Health Service by setting personal interests and

actions of individuals in hospitals to both the level of organizational strategy and state power, showing how roles and practices are "negotiated to meet both personal and organization strategies at the same time, often, as needing to comply with government legislation … meet the demands of the health service … comply with requirements of government bodies" (2001, p. 190). Perhaps surprisingly, the notion of institution is not used in this study, but institutional theory is brought together with the negotiated order perspective to cover similar issues of strategic innovation in public organizations by Grenier to show how actors negotiate and elaborate local and situated agreements to strategically implement new organizational arrangements in institutional contexts introduced by public policies (Grenier, 2011, p. 8). This is a valuable move in that it helps overcome the criticism frequently made of neo-institutional theory that it pays insufficient attention to the part played by action and interaction in processes of institutional change. This is noted by Bechly who shows how combining institutional thinking with the negotiated order concept allows our research fully to acknowledge that people do not directly respond to social structures, but rather to the situations they face and their interpretations of them (Bechly, 2011, p. 1157).

Watson and Watson (2012) echo Bechly's call for multilevel approaches to theorizing. In their study of the interlinking of 'real' beer and public-house-related narratives at the individual level, the organizational/family/group level/community level, and the societal and social change level, they produce an extended version of the concept of negotiated order. The concept of identity-work provides the conceptual focus at the individual level; the notion of the social construction of reality provides the conceptual focus at the societal level; and the extended negotiation of order concept gives such a focus at the middle level. The negotiation of order here is "the pattern of activities and understandings which emerge over time as an outcome of the interplay of the various interests and initiatives of the individuals and groups involved in a group, community, family or organization" (2012, p. 687). Such an extended concept of the negotiation of order, or something like it, has considerable potential for enabling us to appreciate in our research that one cannot understand meanings, actions, and processes within an organization and the way in which order and patterning emerge without observing how the negotiations that occur between all the social actors involved with an organization are intimately related to the negotiated orders of other human grouping in which they are involved, as well as to the structures, cultures, discourses, and narratives that operate at the level of individual lives and at the level of societal structures and processes.

Abstract

The sociology of organizations, like its larger sister the theory of organizations, has seen many different approaches which have left their imprint on our way of thinking about organizations. However, one can distinguish two basic sociological templates in understanding organizations. Within certain limits, the *explanandum* is of course similar. For both, it is the structure and the functioning of organizations but they have different starting points, take different routes, and put the emphasis differently. Thus, the first starts with organizations and will focus on the variation of their forms: as a consequence, organizations are its basic units of analysis and it will analyze the social dynamics on the inter-organizational, sectoral, or societal level in order to explain organizational form. The second, on the other hand, will start with social action and will consider the sheer existence and maintenance of organizations as the basic problem to be addressed: as a consequence, it will concentrate its analysis on interaction processes within organizations, will have individuals (their decisions and their actions) as its basic unit of analysis, and will stress the differences between individual organizations even if they belong to the same organizational field.

The sociology of organizations, like its larger sister the theory of organizations, is not a unified field of research. In its already long history, it has seen many different approaches which have left a more or less profound imprint on our way of thinking about organizations. It is beyond the scope of this article to attempt a complete account of this diversity.

However, taking a distant view, one can distinguish two sociological templates which structure around two understandings of the word organization. The first sees organizations as structural forms, the nature, characteristics, and dynamics of which have to be explained, whereas the second insists on the processes of structuring, i.e., organizing collective human action. Within certain limits, the *explanandum* is of course similar. For both, it is the structure and the functioning of organizations but they have different starting points, take different routes, and put the emphasis differently. Thus, the first starts with organizations and will focus on the variation of their forms: as a consequence, organizations are its basic units of analysis and it will analyze the social dynamics on the inter-organizational, sectoral, or societal level in order to explain organizational form. The second, on the other hand, will start with social action and will consider the sheer existence and maintenance of organizations as the basic problem to be addressed: as a consequence, it will concentrate its analysis on interaction processes within organizations, will take individuals (their decisions and their actions) as its basic unit of analysis, and will stress the differences between individual organizations, even if they belong to the same organizational field.

Both strands have their intellectual roots in the seminal work of Max Weber. In his *Wirtschaft und Gesellschaft* (1964), Weber develops a theory of the forms of legitimate domination in society (traditional, charismatic, and rational–legal forms of domination) which roughly define the bases of the legitimacy of power and influence in a given society and condition the types of organizations to be found within each of these regimes of domination. He then argues that bureaucracy is the organizational form developing within the framework of the rational–legal form of domination and proceeds to give an ideal–typical description of bureaucracy, i.e., a highly formalized and hierarchical form of organization characterized by the predominance of written rules and procedures, formalized tasks, precise definitions of competence, clear lines of subordination, the explicit separation of ownership and management responsibility, and the merit principle as the only legitimate route of access to the different functions in the organization. Weber sees unifying dynamics at work, pushing toward the development and generalization of bureaucratic organizations as they are both legitimate and more efficient. He sees the roots of this greater efficiency essentially in the fact that the arbitrary imposition of power and the resulting interpersonal conflicts are limited by written rules and procedures which allow for more rational, foreseeable, and standardized execution of tasks.

This analysis includes all the themes which organizational sociology has developed and dwelled on through all these years. It also contains the roots for the divide which still structures two traditions in organizational sociology today. One is concerned with the study of organizational forms as they are shaped by the constraints of efficiency (this is the main concern of what has become known as 'structural contingency theory') or legitimacy (this is the theme of the 'neo-institutional school' in organizational sociology). The other tradition emphasizes the study of interaction and decision-making processes which 'produce' as well as 'reproduce' regularities and structure, i.e., organization, and which first developed out of the empirical analysis of public and private bureaucracies.

From the Dysfunctions of Bureaucracy to Organizations as Constructs of Collective Action

In the 1940s and 1950s, bureaucracy was a central theme of empirical study of organizations, especially in the United

States. This has certainly to do with the proliferation of huge administrative bureaucracies and the seemingly unlimited growth of the large corporation which was looked upon with both fascination, and fear. Following Weber's analyses, this movement was interpreted as the proof of the greater efficiency made possible by the standardization, formalization, and depersonalisation characteristic of this form of organization. However, following R. Michels' (1914) iron law of oligarchy, this secular movement raised fears because the conditioning powers of these huge organizations and the oligarchic and technocratic tendencies inherent in their functioning were seen as a threat to democracy and the ideals of reform: organizations as means for collective action in favor of reform set free forces which were in contradiction with these ideals.

The main interest of the early studies of bureaucracy (Merton, 1940; Selznick, 1949; Blau, 1955; Gouldner, 1954, 1955; Crozier, 1961, 1964) was to have considered bureaucracies as a complex social system which had to be studied empirically in order to reconstruct and understand its informal structures and dynamics. Applying the lessons and methods from industrial sociology which developed out of the Hawthorne experiments and the human relations movement sparked by Roethlisberger's and Mayo's account of them, these studies produced results which were in contradiction to both the extrapolations and fears mentioned above. They showed that bureaucracies not only were not always efficient, but also produced informal behavior and dynamics which were often dysfunctional, i.e., detrimental to the attainment of their goals and which in any case created a greater diversity in the ways organizations function than would have been expected on theoretical grounds. Thus, Merton shows that the impersonal rules on which bureaucracies are built induce rigid and ritualistic behavior on the part of their members which are dysfunctional for their capacity to respond to the needs of their clients. Blau demonstrates that the efficiency of bureaucracies is not the product of their formal characteristics but bases his argument on the fact that their members take it upon themselves to break the rules in order to enhance the quality and efficiency of their work.

These studies, however, go beyond merely showing the inefficiencies or deviations of bureaucracies. Following Robert Merton's analysis (1936) of the unanticipated consequences of purposive social action and of the latent functions of social structures, there are two complementary explanations not only for the functioning, but also for the emergence of bureaucracy.

On the one hand, these studies show that bureaucracy is the place (and also the product) of 'vicious circles of bureaucratization,' as the attempts at countering unanticipated and dysfunctional consequences of bureaucratic structures lead to an accentuation of the very characteristics which have generated these dysfunctions. This is, for instance, the mechanism analyzed by Gouldner in his study of a gypsum mine: the formal rules instituted to strengthen control over workers and to fight against their low work morale instead increase the latter's apathy, which management tries to counter by strengthening the surveillance of the workers and an increase in the rules on which this surveillance is based. This attempt, in turn, further increases workers' apathy and passivity, and so on. Crozier's analysis (1964) of the vicious circle generated by impersonal rules and the resulting parallel power relations follows a similar pattern. He shows how the proliferation of impersonal rules in view of eliminating the uncertainties which condition the satisfactory functioning of an organization increases the power of those whose contribution is needed in order to cope with the remaining sources of uncertainty. The interpersonal power and dependence relations which are generated around these uncertainties and the (unofficial and illegitimate) privileges they produce, will justify fears of personal power and dependence relations and therefore increase the pressure for further eliminating remaining uncertainties through centralization and new impersonal rules, which in turn will generate new parallel power relations, and so forth.

On the other hand, these studies explain the bureaucratization of organizations by the latent functions it fulfills for their members. Gouldner (1954) distinguishes five latent functions of bureaucracy: impersonal rules allow for distant control, thus creating a filter and a protection by reducing interpersonal relations; they legitimize sanctions but they also restrict the freedom of behavior of the members of the hierarchy by codifying the possibilities of sanction; they make possible apathy, i.e., behavior which restricts itself to the strict application of the rules; and therefore they are a resource for bargaining with members of the hierarchy if they need some extra commitment, which they always do. Moreover, Gouldner shows that bureaucratization is an answer for the problem of succession in organizations, in so far as impersonal rules can at least partially be a substitute for the personal legitimacy which the outgoing managers enjoyed, but which the incoming managers lack. Crozier's analysis (1964) follows a similar pattern but completes Gouldner's interpretations with a broader theory: the bureaucratic mode of organization based on the proliferation of written rules and procedures is a way to avoid face-to-face relations and to escape the arbitrariness and uncertainties of direct power and dependence relations. Its latent function is a general one and relates to the necessity of taming and structuring the power and dependence relations which are at the heart of collective action and without which no cooperative endeavor is feasible.

The essential merit of these seminal studies is to enable us to go beyond the sterile opposition inherited from the human relations tradition between, on the one hand, formal structure understood to be the incarnation of rationality as well as efficiency and, on the other, the actual behavior of its members which result from their irrationality, their affectivity, and their conditioning by prior processes of socialization. In their theorizing, the rationality of formal structure is no more opposed to the affectivity of human behavior. On the contrary, they interpret these structures as an answer to the cognitive limits and to the constraints stemming from human affectivity. The structure and the goals of an organization can thus no more be understood as the expression of a logic which could be independent from, and superior to, the relations between the members of an organization. They are created by these relations and draw their significance and their justification from them. In short, they are no longer an exogenous variable. They have been put back into the dealings between the members of an organization and become the endogenous result of them: they

cannot be understood independently from the interaction and bargaining processes for which they constitute only the framework. They therefore cannot escape the limits of rationality characterizing the human behavior which produces them, and have to be analyzed together.

One can clearly see the thrust of this line of reasoning. Drawing on these studies of bureaucracy as well as on the seminal work of the Carnegie group around H. Simon on a behavioral theory of decision making in organizations (March and Simon, 1958; Cyert and March, 1963) and on the analyses of collective action and public or private decision making in the United States and in Europe (see Allison, 1971; Crozier and Friedberg, 1977; Grémion, 1976; Hirschmann, 1967, 1970; Lindblom, 1959; Olson, 1965; Schelling, 1961, 1978), it points toward a behavioral conceptualization of organizations which links organizational behavior to the cognitive and relational capacities of their members. An organization, in this view, can be understood as an arena (Cyert and March, 1963) or as game structures (Crozier and Friedberg, 1977, 1995), where participants are free to choose their behavior, but within limits. The range of their choices is restricted, because if they do not want to lose in the transactions with the other participants, they have to take into account the rules of the game which prevail and which determine the value of the resources of each participant and the appropriate ways of using them in transactions with other participants. But within these limits, which may be variable and leave more or less leeway, they can and will actually choose their behavior which can thus be understood as the way in which they adjust to the constraints of their situation as they see it, while simultaneously trying to further their interests (in whatever way they may define them) by using the resources and opportunities they perceive. Their behavior therefore cannot be considered as completely hazardous: it is the expression of a decision which makes sense to the person who is choosing and therefore is rational in the sense of H. Simon's bounded rationality (Simon, 1957; March and Simon, 1958). It is a reasonable adjustment by any participant to his or her situation; i.e., the network of interdependencies within which each participant is located, an adjustment which is reasonable within the limits of his or her perception of the opportunities and constraints contained in this situation and of his or her capacity to make use of these opportunities and constraints.

Such an approach to organizations, which emphasizes the constraints on organization resulting from the limited (but extendable) cognitive and relational capacities of human beings, naturally transcends the usual distinctions between different forms of organizations (hospitals, firms, administration, etc.), and its heuristic value clearly is not limited to the analysis of formal organizations. Its target is, in fact, a much broader issue which all kinds of organizations and all forms of collective action have to solve; i.e., the problem of cooperation and coordination between actors pursuing and continuing to pursue divergent interests. It is, in a way, centered around a theory of the organizational phenomenon which aims to understand how participants who continue to pursue divergent interests can nonetheless organize or accept to be organized in the pursuit of collective goals. Such an approach radically banalizes formal organizations which, in this view, are only one of many possible forms of contexts of action the characteristics of which constrain the collective action of the various participants (Friedberg, 1993). Organizations thus become the artificial device which help analyze and understand the general problem of human cooperation and coordination. Organizational sociology becomes a way of theorizing about collective social action.

Efficiency and Legitimacy as Unifying Forces Shaping Organizational Forms

The other tradition, to which we will now turn, has a different starting point. It sees organizations as structural forms, the nature, characteristics, and dynamics of which have to be explained. Thus, it starts with organizations and will focus on the variation of their forms: organizations are its basic units of analysis and it will try and analyze the social dynamics on the inter-organizational, sectoral, or societal level in order to explain organizational form. These dynamics are traced to two distinct constraints: efficiency and legitimacy, each of which is stressed by a different strand of analysis.

Efficiency is the constraint stressed by structural contingency theory. This paradigm emerged in the middle of the 1960s and developed as a critical reaction to the theoretical and methodological perspective characteristic of organizational sociology of the 1950s. With regard to methodology, the then dominant qualitative case-study method was criticized because it provided merely a thick description but no grounds for generalizations or for the construction of a general theory of organizations. With regard to theory, it was argued that the over-emphasis on motivations and human relations characteristic of organizational thinking so far had had two consequences detrimental to our understanding of organizations: the role of structure and its influence on these relations had been downplayed, while, and this was seen as even more important, the context of an organization and the way its characteristics condition an organization's structure and functioning had been largely ignored.

As a consequence, structural contingency theory set out on a different program. Its focus was not on action or behavior within organizations, but on organizations as structured entities whose characteristics and change over time have to be explained using quantitative methods for the statistical study of samples of organizations in order to list, describe, and, if possible, measure the influence which the main dimensions of an organization's context exert on its structures, its functioning, and its performance. In other words, this paradigm was concerned with two main questions: which dimensions of context affect an organization's (mainly structural) characteristics and to what extent? what is the influence of each of these characteristics on the performance of an organization?

Structural contingency theory has been the dominant paradigm in the field of organization studies from the middle of the 1960s up to the first half of the 1980s, especially in the Anglo-Saxon world. It has generated an immense effort to determine and measure the impact of the various dimensions of context. Let us mention a few particularly significant research programs. The influence of technology on the structure of

organizations has been explored by J. Woodward (1958, 1965, 1970) and C. Perrow (1967, 1970); the Aston group around D. Pugh (1963) and D. Hickson et al. (1969) as well as P. Blau in the United States (Blau and Schoenherr, 1971) has explored the link in particular between size (among other, less central variables) and organizational structure. The impact of the technical, economic, and social characteristics of an organization's environment on its structure and mode of functioning have been independently studied in the seminal work of Burns and Stalker in England (1961) and Lawrence and Lorsch in the Unites States (1967). Last, but not least, the more conceptual work of J. Thompson (1967) has also been very influential, especially in regard to his conceptualization of what he called the 'task environment' of an organization. This approach is developed further by the population ecology of organizations, which builds on the seminal work of Aldrich (1979) as well as Hannan and Freeman (1977) and which aims at studying the contextual conditions which explain the emergence, the diffusion, and the disappearance of populations of organizations which share the same characteristics and which fit certain contextual conditions or ecological niches.

The main contribution of this quantitative and apparently more scientific approach to the study of organizations has been to demonstrate empirically the impossibility to define a single best way for structuring an organization. The good, i.e., the efficient structure, cannot be defined in general and beforehand. It is a function of the context and can only be defined after the different dimensions of this context have been recognized and taken into account in the organizational design. However, this very important contribution should not cover up the theoretical and empirical shortcomings of the approach. Indeed, according to the reasoning on which it is based, context becomes a constraint because organizations are viewed as driven by the constraints of efficiency. Indeed, so this reasoning goes, organizations have to adjust to their contexts because their performance depends on this fit: in order to survive, they have to be efficient and, in order to be efficient, they have to adjust to the demands of their context. Although there is certainly some truth in this hypothesis, the empirical diversity of organizations with similar contexts has shown that structural contingency theory has vastly overestimated the unifying power of the constraint of efficiency. It has enlarged our understanding of the forces which shape organizations but in the process has overstated its case and has been proven wrong by empirical analysis.

Against this reductionism, which pretends to analyze organizations from a purely technical or economic viewpoint (the pressure of the constraint of efficiency), the neo-institutional school in organizational analysis has promoted a more sociological perspective. It emphasizes the symbolic and normative dimensions of action in and between organizations, and stresses the role of their culture, i.e., a set of cognitive and normative frames, to explain their mode of functioning. In other words, it puts forward a less intentional and rational perspective on organizations. In this view, organizations are neither the simple tools of their masters nor machines to maximize efficiency. They are also institutions, i.e., social worlds with their specific identity and culture, which, once created, take on a life of their own and develop their own ends which can never be reduced to mere considerations of efficiency.

Sociological neo-institutionalism builds on, and tries to integrate, several theoretical perspectives: the work of P. Selznick (1943, 1949) on organizations as institutions, the work of H. Simon and his group at Carnegie on bounded rationality and cognitive frames, and the work of Berger and Luckmann on the processes of institutionalization understood as processes of the social construction of reality. In organizational analysis, it brings together the work of American and European sociologists, such as N. Brunsson, P. DiMaggio, N. Fligstein, J. G. March, J. Meyer, J. P. Olsen, W. W. Powell, B. Rowan, W. R. Scott, and L. G. Zucker, whose analysis of organizations is based on roughly three main premises.

First, an organization is an institution because it is structured by a set of cognitive, normative, and symbolic frames, which shape the behavior of its members by providing them with the tools necessary to observe and perceive the world around them, to interpret and understand their counterparts' behavior, and to construct their own interests as well as possible ways to further them. Through their structures – formal (organizational forms, procedures, institutional symbols) as well as informal (myths, rituals, social norms) – organizations shape the perceptions, calculations, reasoning, interpretations, and actions of their members by defining acceptable and legitimate behavior, i.e., behavior which is appropriate in the context of its culture.

Second, no organization exists independently of other organizations which share the same characteristics and which together form an organizational field: e.g., the organizational field of universities, hospitals, schools, airlines, museums, etc. Such organizational fields have their producers and consumers, cognitive and normative frames, their power structures, control mechanisms. In short, they have their own institutional structure and their own dynamics which are brought about by competition as well as interdependence between the constitutive organizations, processes of professionalization, i.e., the establishment of cognitive and normative frames for the field, by government intervention and the like. The dynamics of these organizational fields exert unifying pressures on the individual organizations which, in order to enhance their legitimacy, tend to adopt similar, if not identical, institutional forms and procedures.

Third, while recognizing the importance of the technical and economic environment which was stressed by the structural contingency theory, the neo-institutionalist perspective is interested mainly in the influence ofthe societal and institutional environment. The institutional environment concerns the characteristics of the organizational field of which an organization is a part, and of the rules it has to follow if it wants to obtain resources from the field and strengthen its legitimacy in it. The societal environment designates the norms and values of modern societies which, according to DiMaggio and Powell (1983) or Meyer (Meyer and Scott, 1994), are characterized by processes of rationalization (to a certain extent, this can be understood as the reedition of Max Weber's process of the disenchantment of the world) and the diffusion of standardized norms as a consequence of increased intervention by states, professions, science, and organizational fields. Both institutional and societal environments constitute a sort of unifying matrix for

organizations which have to conform to their pressures if they want to be accepted and thus able to draw resources for their functioning.

In short, the neo-institutional perspective stresses the constraint of legitimacy, as opposed to the constraint of efficiency. Rational structures (formal organizations) do not dominate the modern world because they are efficient. They adopt rationalized institutional norms because these will enable them to obtain the resources necessary for their success and their survival as they increase their legitimacy in a wider cultural environment (rationalist Western society and culture).

Taken together, the two strands of reasoning mentioned in the opening remarks provide a complete panorama of the forces shaping organizations: efficiency and legitimacy are the constraints, within which the games being played in and between organizations are embedded, but the games that depend upon the cognitive and relational capacities of the individuals playing them are in turn mediating these constraints. The unifying forces stressed by contingency theory and the neo-institutionalist perspective should therefore never be overestimated: they are themselves subject to differentiating pressures stemming from the cognitive and relational capacities of the humans who play games in contexts structured by constraints of efficiency and legitimacy. These relational and cognitive capacities are never determined and are never final: they are the motor for the infinite variance which is observable in organizational life, they are the motor of innovation which succeeds in destabilizing even the best established technical or institutional environments.

Organizations: Unintended Consequences

Abstract

Organizations are often constructed to make up for the unintended, sometimes perverse consequences of individual actors being unable on their own to act in their common interest; yet organizations produce *de novo* similar and new unintended consequences among and within themselves, as well as for society at large. It is not the problem as such but its manifold manifestations that is of interest, as well as their explanation. The multifarious forms of unintended consequences can all be subsumed under the problem of rationalization. A useful typology containing the basic configurations of unintended consequences has six dimensions: (1) the number of individual actors that realize their goals. (2) whether they are positive and/or negative; (3) number of other actors affected; (4) whether they are predictable; (5) the time it takes for them to develop; and (6) whether the focal actor is the corporate actor itself, or a set of individual members. Sociology provides empirical research on concrete instances, for example, oligarchic tendencies, rate-busting, and the performance paradox, whereas economics produces theoretical accounts, for example, external effects, transaction cost theory, and agency theory. Sociology focuses more on unanticipated consequences and explains these by referring to the lack of or faulty information. Economics concentrates on unintended yet frequently anticipated consequences that stem from devious incentive structures.

Unintended consequences are the grand theme of sociology. Like all social sciences sociology assumes that people act intentionally; however, in sociology these actions are seen to be socially conditioned, and while people act upon their intentions they produce unanticipated, unintended, even perverse consequences. While the notion of social conditioning has become part of the western worldview, this has not been the case for the notion of unintended consequences.

Organizations are often constructed by people to make up, through the pooling of resources, for the unintended consequence of individuals being unable to act in their common interest. Yet organizations produce new second-order unintended consequences in and among themselves and for society at large (Scott, 2014).

History of the Problem within Sociology

Interest in unintended consequences started in the eighteenth century with the individualistic tradition of the Scottish moral philosophers. In accord with Bernard de Mandeville's words, "private vices, public benefits," Adam Smith analyzed the unintended benign effects of the free market: as if moved by a hidden hand free trade transforms the self-centered motives of individual actors into a greater wealth for all. The French contract tradition provided other insights. Condorcet showed that when parties, each with consistent but different preferences on various issues, come together to collectively decide upon them, preferences on the collective level might be inconsistent, resulting in voting cycles. Rousseau described *avant la lettre* what is now known as a prisoner's dilemma, a situation in which individual and collective rationality conflict. Two persons while hunting deer fail in their objective because instead of cooperating – what they agreed upon and what is necessary to catch such a big game – one of them is tempted by the immediate gain of catching a hare. The unintended outcome is that both are collectively worse off than they could be. Thereafter, collectivist traditions prevailed. Hegel hinted at unintended consequences in his work on the long-term historical development when he spoke about the 'cunning of reason.' However, he did not analyze why they emerge. Marx adopted these ideas of laws in history and the notion that people make history without being aware, with one exception: under communism people can decide upon their common plan and escape from unintended consequences because they are unfettered by unjust power differences. The Durkheimian program of collectivist sociology did not encourage students to look for or analyze unintended consequences; although many of the phenomena Durkheim described can be reconstructed as being the unanticipated, unintended outcome of individual actions, for example, the solidarity that flows from ceremonial gatherings, or a rise in suicide rate after an economic boom, a so-called *crise heureuse*.

Merton (1949) placed the theme back on the research agenda with his analysis of manifest and latent functions; that is, consequences of individual actions that are either intended and recognized or unintended and unanticipated. He provided case studies of self-fulfilling prophecies, such as customers beginning a run on a bank they wrongly believe to be insolvent, causing it to go bankrupt, or the Mattheus effect in science, that is, how fame begets fame.

About the same time Elias presented his general ideas on unintended consequences in a historical study on state-formation and the refinement of manners. According to him unintended consequences, for example, refined manners, will be more common in larger groups, with more complex social networks, and smaller power differentials.

Lately, with the emergence of a rational choice sociology and organizational economics, unintended consequences become more central to research, although often under different headings (*see* Rational Choice and Organization Theory; Long et al., 2014).

Unintended Consequences in Organizations

Even a cursory review of the research literature shows that unintended consequences in organizations come in many forms and with multiple origins.

In the wake of Weber's discussion as to why Marxism did not succeed in its revolutionary goals, Michels (1911) formulated the iron law of oligarchy, probably the most famous instance of an unintended effect. This 'law' states that with time and growth of the organization there will be oligarchic tendencies in every organization, also in socialist organizations with a democratic ideology and constitution. Why is it rational not to be interested in one's own interests and not use one's democratic rights? Over time and with growing size it becomes less practical that all participate, and even leaders have to specialize and delegate. As the social distance between members and leaders grows, the cost for members to stay informed and to coordinate their actions increases. This gives discretionary power to the leaders also, if they only have eyes for the interests of the members. There are, however, exceptions to the iron law, like the ITU, the union of typographers that was studied by Lipset et al. (1956).

Just before World War II, industrial sociology discovered the informal group in formal organizations. Informal relations sometimes go against the objectives of the firm as they lead to rate busting. Yet, other research underlined their productive contribution. The work-leader's centrality within this informal network seems critical: employees will cooperate more readily and management can keep track of ties between employees (*see* Network Analysis).

Since informal networks can have negative consequences, a work leader has to keep track of and control all the possible ties between employees and, therefore, his span of control should be limited. Research showed an intricate unintended relation between span of control, levels of hierarchy within an organization, and level of pay: a smaller span of control leads to a taller hierarchy and greater wage differentials in an organization. Promotion schemes are another known source of unintended consequences. Stouffer (1949) gave the classic example of soldiers who were less satisfied and had lower morale in companies with a higher rate of promotion. To evaluate their own status as well as to estimate what actions would be in their own interest people compare themselves to similar others. They care for relative, and not for absolute status. Recent research, however, could not replicate Stouffer's findings. Even those who are not promoted interpret high promotion rates as a sign of trustworthiness of the employer.

Lately, an important instance of unintended consequences in organizations has been discovered, that is, the performance paradox (Meyer and Gupta, 1994). Where performance of a department or organization can be established, somehow measurements run down over a period of time for a number of reasons: (1) positive learning, that is, as performance improves, indicators become less useful, (2) perverse learning, that is, performance seems to improve without actually doing so because employees or managers adapt to the measurement system and learn how to fix the indicators, and (3) selection or replacement of poor performers for better performers. Often these processes occur simultaneously (Harbour, 2009).

A Typology of Unintended Effects

It is not the problem as such but its manifold manifestations, their explanation, and how they can be amended that is of interest. Yet the various forms of unintended consequences have a common denominator in that they can all be subsumed under the problem of rationalization, since they affect efficient goal attainment.

A useful typology that covers the basic forms should at least have six dimensions (Boudon, 1977):

1. number of individual actors that realize their goals,
2. whether the effects are positive, negative, or both,
3. number of actors affected by the outcomes,
4. whether they were anticipated or not,
5. the time it takes for consequences to develop,
6. whether a corporate actor or individual persons are the focal actor(s).

Explanation Sketches in Sociology and Economics

Existing theoretical knowledge on unintended consequences is not well integrated. The accounts given refer to a number of recurring elements, though: lack of or faulty information and incentives to act opportunistically. Sociologists traditionally focus on the former, and recently economists have emphasized the latter.

Until Coase explained why organizations exist, economists were silent on what happened in organizations. They exist because they are more efficient in certain situations as they save not only on production costs but also on transaction costs stemming from recurrent transactions and transaction-specific investments (*see* Hierarchies and Markets).

Economists made clear that there are dilemma situations in which consequences emerge that are unintended but foreseen. The employment relation, for example, is fraught with anticipated, yet often inevitable unintended effects. Employer and employee are collectively better off if they trust each other and cooperate, yet each is tempted by opportunism.

Firm-specific investments in human capital made by the employees can, depending on the alternatives both have, be misused by both parties against the other. An employer may cheat upon his promises just as the employees may sometimes shirk work or reverse who controls whom.

What situational characteristics lead to these deficits in information and incentives to act opportunistically? The examples of unintended consequences discussed either stem from functional, cognitive, or structural interdependencies between various actors (Lindenberg, 1997). People need each other to cooperate in the attainment of a common goal, to acquire or reduce information, and to get advice, gain approval, or emotional support. Moreover, persons who are functionally interdependent, for example, in their tasks, will interact and it will also affect their mind.

Another relevant distinction is whether the unintended effects of a transaction affect only those involved in the transaction or also other third parties. Economists call the latter 'externalities.' Sociologists would consider them third-party effects. Actors do not want to be responsible for negative

externalities but they would like to internalize positive ones (Opp, 2002).

If groups grow in size, Olson (1965) showed that this logic will keep people from contributing to the common good. Many unintended effects in organizations come from the outside as external effects; for example, growing time pressure and growing wealth in society at large make people want to trade time for money resulting in many voluntary organizations nowadays being 'check book writing organizations.'

Many unintended effects come about through path dependency of social processes; that is, effects of earlier choices feed back into the social situation under which individuals decide on their next move, augmenting original differences, as with, for example, oligarchic tendencies.

Why are there exceptions to unintended effects? From the relevant research literature one might take the following advice. To come up with explanations one could stick to a behavioral theory of action and think about who are relevant actors, what are their goals, what actions would further these goals at what costs given the situation, and what actions would constitute the unintended effect. Oligarchy, for example, is reflected by nonparticipation by members and leaders not acting upon members' interests. In the case of the ITU, for example, the three kinds of interdependencies came together such that the difference in knowledge and political experience was far less than usual and that leaders were also part of the informal groups. All these are conditions that promote a choice for the democratic alternative. The absence of voting chains that might complicate originally democratic choices also helps (see Wippler, 1986).

What can be done about negative unintended effects? It makes a difference whether there are central agencies that try to stabilize, correct, or foreclose the emergence of unintended negative outcomes. Functional interdependencies can be changed through social technology, for example, through redefinition of rights of actors (*see* Design and Form: Organizational).

Cognitive and especially structural interdependencies are harder to manipulate. As can be learned from principal agent and transaction cost theory, many unintended effects in organizations come from the split of ownership and usage rights, or more generally from the split between authority and responsibility. Organizational rules can redefine property rights and thereby align interests such that those who have control right over a productive capacity also have an interest in employing this capacity in a productive way. A simple application of this advice is to bind salaries of managers to performance of their department or firm. Another one is to make employees not responsible for mistakes made by others; for example, in a sequential production process a system of quality control through backward policing allows employees to refuse products delivered by others (see Milgrom and Roberts, 1992).

Abstract

Interest in Europe in the study of the 'Orient' as both a geographical and an imaginary space has a long and contested history. Orientalism, or Oriental Studies, evolved as an interest in the languages and cultures of the region. By the eighteenth century, with the invasion of Egypt by Napoleon, European imperial expansion had created the opportunity for travel and a new need for analysis. Edward Said's seminal book *Orientalism* (1978) sparked a critique of academic Orientalism and its political implications. The ongoing debate, despite flaws in Said's presentation, has had a positive impact on academic study of the regions once assumed to be an unchanging Orient.

Orientalism is a contested term, primarily because of its imaginative geographical reference to a variety of major civilizations in the east of Europe. By the eighteenth century, the term referred primarily to scholarship that studied and used so-called Oriental languages. The reputed founders of Western Orientalism, such as Guillaume Postel (1510–81), Abraham-Hyacinthe Anquetil-Duperron (1731–1805), and William Jones (1746–97), were all philologists. By the nineteenth century, several societies devoted to the study of Oriental languages and cultures had been established in Europe, including the Société Asiatique in Paris (1821), the Royal Asiatic Society of Great Britain and Ireland (1823), and the Deutsche Morgenländische Gesellschaft in Leipzig (1845), as well as the American Oriental Society, founded in 1842. In 1873, the first International Congress of Orientalists was held in Paris. The papers covered ancient and contemporary Near Eastern civilizations, India, Southeast Asia, China, Japan, modern Greece, and an array of ethnographic examples including *sauvages océaniens*. As a term, *Orientalism* also has several specific usages for periods, including the early phase of British involvement in India from 1784 to 1835, before the Anglicanism exemplified by the ethnocentric Lord Thomas Babington Macaulay (1800–59). The genre of nineteenth century European art characterized by exotic harem beauties and Bedouin sheikhs on horseback is styled Orientalist, especially the paintings by Jean Auguste Dominique Ingres (1780–1867).

The primary interaction between Europe and the so-called Orient focused on the Near East. Christian pilgrims routinely visited the sites of the Holy Land in Palestine. Trade flourished in the Mediterranean after the spread of Islam into Spain in the first part of the eighth century CE. Much of the early scholarly interest came from Christians opposed to Islam, including the 1143 CE Latin translation of the Quran commissioned by Peter the Venerable (Kritzeck, 1964). The formal university study of Arabic in Europe, for example, did not begin until the Church Council of Vienna in 1312; the first Sanskrit text translated into a European language appeared in the seventeenth century. By the time of Napoleon's invasion of Egypt in 1798, a defining moment in European colonial involvement in the Orient, Arabic was taught at most of the major European universities. As Samir Amin (1989: 100–101) argues, the term *Orientalism* should not be conflated to include all study by Western authors of people encountered to their east, but rather to "the ideological construction of a mythical 'Orient,' whose characteristics are treated as immutable traits defined in simple opposition to the characteristics of the 'Occidental' world."

Oriental studies in an academic sense evolved primarily as philology, closely related to the long-standing interest of both Christians and Jews in Hebrew and Aramaic. The expansion of European states into the Orient created a need to translate and understand major languages, such as Arabic, Persian, Sanskrit, and Chinese. In the nineteenth century, archaeological discoveries led to decipherment of several ancient Near Eastern languages, including Egyptian hieroglyphics and Akkadian. Fascination with the customs of the 'Bible Lands' created a popular genre of writing by travelers and missionaries such as William Thomson's (1859) *The Land and the Book*. Several travel accounts of the Near East were widely read in Europe and America, including Richard Burton's (1855–56) account of a secret visit to Mecca in 1853, Mark Twain's (1869) satirical account of a steamship tour to the Holy Land, and Charles Doughty's (1888) eloquent account of travels in the interior of Arabia.

A wide range of academic texts have been published in the broad field of Oriental studies, which many universities have renamed Asian, Near Eastern, or Middle Eastern studies in the past four decades. For Islam and the Middle East, the most authoritative source is *The Encyclopedia of Islam*, originally published between 1913 and 1938 in English, German, and French, a second edition published between 1954 and 2005, and a third edition began in 2007. Brill's *Handbuch der Orientalistik* series has published, since 1952, monographs concerning the civilizations of the Near East and Asia. Brill also published the *Index Islamicus*, a bibliographic database that extended back to 1906 and currently covers more than 3000 journals. Although dated, the guide to resources by Jean Sauvaget (1965) is still useful for earlier references to Islam in the Middle East and North Africa.

Edward Said on Orientalism

In 1978, the literary scholar Edward Said (1935–2003) published his seminal *Orientalism*, a book that redefined and reshaped the study of Orientalism as an intellectual field of study. Said (1979: p. 1) broadened the preexisting sense of Orientalism beyond philological and area studies and suggested that the Orient 'was almost a European invention.' The core of his argument is that the word *Orient*, as used in European and American discourse,

should be labeled *Orientalism* and should not be confused with the 'real Orient.' Said situates his critique of the European invention of the Orient as someone who is an Oriental in two senses. First, he himself is stereotyped according to the ethnocentric and racist bias that is often found both in popular media and in some academic forums. In response to a later critical review, Said (1982: p. 45) sarcastically refers to critics like Bernard Lewis and Clifford Geertz as treating him like a 'wog,' a racial epithet used by the British against Arabs and North Africans. The second sense is what authorizes Said, a literary critic with little academic knowledge of the history of Oriental studies, to be taken seriously; the author is an Arab Palestinian, whose repulsion at the stereotyping is thus not "an exclusively academic matter" (Said, 1979: p. 27). Largely because of his public stand for Palestinian rights, Said has been labeled as Professor of Terror and has received death threats. The Orient, as invented, may not exist, but flesh-and-blood Arabs, Palestinians, and Muslims certainly do.

At the start of his text, Said (1979: pp. 2–3) presents three working definitions for *Orientalism*. The first, by virtue of its being 'most readily accepted,' is seemingly academic: "Anyone who teaches, writes about, or researches the Orient – and this applies whether the person is an anthropologist, sociologist, historian, or philologist – either in its specific or its general aspects, is an Orientalist, and what he or she does is Orientalism." The gist here is that Orientalism is what Orientalists do, and that whatever Orientalists do is Orientalism. Such a tautology provides the critic virtually unlimited ground for maneuvering among a wide variety of texts no one previously would have grouped together. Thus an Arabist like Edward Lane (1801–76), whose Arabic-English lexicon is still definitive after a century and a half, can be lumped together with a libertine novelist such as Gustave Flaubert (1821–80). Also new was the idea that anthropologists and sociologists, who rarely looked at Oriental texts, were doing essentially the same thing as those who did. Orientalism is further assumed to permeate all corners of academe and live on 'through its doctrines and theses about the Orient and the Oriental.'

The second sense of *Orientalism* proposed by Said is a general but more straightforward reduction of Orientalism to "an ontological and epistemological distinction made between 'the Orient' and (most of the time) 'the Occident.'" The epistemological dimension is self-evident; such a division had been widely used for centuries as an imagined cultural overlay on geographical space. Said (1979: p. 57) focused on the fifth century BCE play *The Persians* to argue that the East–West divide goes back to classical Greek culture. But the term *Oriental* was not used to refer to the inferior other by the Greeks; their term was *barbaros* (precursor of the modern term *barbarian*) and was not reserved for the Persians and other peoples to the east of Greece (Romm, 1998: pp. 95–96). Said adopts what historians call a Whiggish perspective, looking at the history of relations between peoples in Europe and the Near East through the filter of a post-Enlightenment, imperialist age of European empire. This distinction between East and West is necessarily relational but not always essential. In the realm of representations, which Said addressed in his book, the philosophical debate about ontology is not discussed. Even so, as Johannes Fabian (1999: p. 38) comments, on a different author in a different context, "ontology does not get us through the day." The point is that distinguishing Western self from Eastern other is an obvious epistemological rather than a dubious ontological issue.

It is the third meaning of *Orientalism* that fully engages the critical acumen of Said and most excites and incites his readers. The two generalized senses of *Orientalism* as whatever Orientalists do and what they always do to an Orient are situated 'historically and materially' in the colonial expansion of Britain and France over the past two centuries. Orientalism is now fully exposed "as a Western style for dominating, restructuring, and having authority over the Orient" (Said, 1979: p. 3). Style is, of course, too light a term to denote the politically charged sense of hegemonic ideology that Said's literary imagination conjures out of Michel Foucault's notion of discourse and Antonio Gramsci's elaboration of hegemony. Said employs 'discourse' to argue that Orientalism is an institutionalized force present in every Western author who writes about the Orient. Although differing in principle with Foucault, Said's (1979: p. 23) stated belief in the "determining imprint of individual authors" does not extend to even the most sympathetic of scholars such as Louis Massignon (1883–1962). Indeed, Said (1979: p. 319) argues that Orientalism is "a dogma that not only degrades its subject matter but also blinds its practitioners." In the same vein, Said (1979: p. 307) writes, "Of itself, in itself, as a set of beliefs, as a method of analysis, Orientalism cannot develop. Indeed it is the doctrinal antithesis of development." The primary reason for this is the cultural hegemony of Europe as an imperialist and colonizing power in the real Orient, which is assumed to be a passive victim.

Akbar Ahmed (1992: p. 185) observes that Said suggests mainly what this style is not, so we are told it is not what colonialist ideology says it is. It is not objective and not concerned with the real Orient. "Indeed," admits Said (1979: p. 12) "my real argument is that Orientalism is – and does not simply represent – a considerable dimension of modern political-intellectual culture, and as such has less to do with the Orient than it does with 'our' world." The fundamental corollary of Orientalism's stylistic production of the Orient is, despite Said's ontological tease, its representational function as 'a sort of surrogate and underground self' to imperial Europe. As the Syrian scholar Sadiq Jalal al-'Azm (1984: p. 351) observes, "Certainly Homer, Euripides, Dante, St. Thomas, and all other authorities that one may care to mention, held the more or less standard distorted views prevalent in their milieus about other cultures and peoples." As several critics have countered, there was an equal disdain of Europeans by peoples living in the so-called Orient.

Said noted that his threefold definition "will become clearer" later in his text. The focal point of this clarification, in Said's own words (1979: p. 206), occurs in his distinction between latent and manifest Orientalism:

> The distinction I am making is really between an almost unconscious (and certainly an untouchable) positivity, which I shall call *latent* Orientalism, and the various stated views about Oriental society, languages, history, sociology, and so forth, which I shall call *manifest* Orientalism. Whatever change occurs in knowledge of the Orient is found almost exclusively in manifest Orientalism; the unanimity, stability, and durability of latent Orientalism are more or less constant.

By *manifest*, Said refers to those parts of Orientalist discourse that can be negotiated, viewed differently, or even debated. The manifest comprises the material elements of Orientalism: texts, authors, guilds, the apparatus of academic disciplines, professional societies, the publishing industry, colonial administrative structure, and the like. Said draws examples from these material elements, especially texts, but his whole point is that nothing manifest makes sense without grounding the whole complex in the latent 'positivity' that ultimately defines it as hegemonic discourse. Unlike his use of Foucault's term *discourse* and Gramsci's term *hegemony*, the borrowing of the terms *manifest* and *latent* is not itself made manifest in *Orientalism*. These are, of course, terms laden with meaning in the psychoanalytic interpretation of dreams, especially in Lacan's reworking of Freudian theory (Yegenoglu, 1998: p. 23).

Critiques of Said's Orientalism Thesis

Said's Orientalism quickly became required reading in a number of fields and is credited as a founding text of postcolonial studies. The text, which was never revised but did receive from Said an afterword in 1994 and a preface in 2003, is available in at least 36 languages. Aijaz Ahmad (1992: p. 14) refers to Said as the central figure influencing the study of postcolonial literature. The visibility of Said's text was heightened by the increased attention paid to political events in the Middle East during the 1970s, including the 1973 Ramadan war and Arab oil embargo, the civil war in Lebanon, the jihad against the Soviets in Afghanistan, and the Iranian Revolution of 1979. The initial reviews, of which there were more than 50, were mixed. Most praised the effort of Said to expose the blatant ethnocentrism and racism in much of the previous literature on the Orient, but many pointed out historical errors and Said's lack of familiarity with the academic genre. "The basic problem," wrote historian Richard Bayly Winder (1981: p. 618), "is that *Orientalism* is a polemic, in a good cause, but a polemic."

The most caustic critic, historian Bernard Lewis, was a target of Said's disdain. Lewis is dismissed by Said (1979: p. 316) as having "a project to debunk, to whittle down, and to discredit the Arabs and Islam." As an example, Lewis is criticized for saying in a minor conference article that one of the Arabic terms for *revolution* in a political sense has an etymology that refers to the awkward rising of a camel. "Instead of revolution there is sedition," writes Said (1979: pp. 315–316), "setting up a petty sovereignty, and more excitement, which is as much as saying that instead of copulation the Arab can only achieve foreplay, masturbation, coitus interruptus." Said attributes a sexual slant to the editor of the conference's proceedings as well, ignoring the editor's observation that the concept of revolution in European usage "attempts to create substitutes for reality: to control the known world by bringing it under its history-moulding will" (Vatikiotis, 1972: p. 8). Not only does this view resonate with Said's own approach to Orientalism as discourse, but in fact the 'bad kind of sexuality' that Said teases out of the passage would target revolutions in Europe and not in the Middle East. Lewis (1982) waited three years before responding to Said in print, fueling the personal antagonism that dominates their exchanges.

Anthropologists, while respecting Said's critique of Western ethnocentrism, have for the most part faulted Said for his lack of knowledge about ethnography and anthropological theories of culture. The 'rise of ethnography' is traced by Said (1993: pp. 44, 108) to Gobineau, Maine, Renan, and von Humboldt – none of whom actually did ethnographic fieldwork or provided methodological models embraced by modern anthropology as a formal discipline. Said's view of culture is based on the elitist literary definition by Matthew Arnold, with no concern for the evolution of cultural concepts within anthropology since Edward Tylor (Varisco, 2004). George Marcus and Michael Fischer (1986) begin their book *Anthropology as Cultural Critique* by citing the 'broad and indiscriminate' brush used in Orientalism to attack Western representation of the Orient. Michael Richardson (1990: p. 17) accuses Said of "as much mis-representation of Orientalists as he accuses them of making in their representations of the Orient."

One of the few anthropologists to speak positively about Said's methods as a literary critic useful for anthropologists is Lila Abu-Lughod. After Said's 1987 lecture at the annual meeting of the American Anthropological Association, Abu-Lughod (1993: p. 10) engaged, at Said's suggestion, to write against essentializing discourse in anthropological theory. The specific notion of culture that Lila Abu-Lughod is writing against is one that most anthropologists would concur needs to be delegitimized. Unlike Said, she notes that cultural anthropologists have long questioned the idea of scientific objectivity, have consistently opposed racism, and have developed a reflexive critique of their own discipline. Said, who is not alone, is right to question the damaging binary of West vs East as an imaginative geography that necessarily instates a difference based on power. Yet Abu-Lughod is writing primarily against an assumed tendency to essentialize or freeze cultures rather than the common anthropological position that human beings all share, in their collective evolution, a qualitative cultural distinction. Andrew Shryock (1997: p. 314) suggests that Abu-Lughod is essentially writing against 'androcentric, agonistic discourse,' adding that this "slights a world of experience and concern; moreover, it renders much of intellectual and political life in the Middle East immediately unintelligible."

Numerous critics have noted that the central problem with Said's Orientalism thesis is not that there was no prejudicial writing about the imagined Orient, but that he essentializes Western Orientalists as part of a homogeneous discourse, a kind of Orientalism in reverse. Said has been praised for applying Foucault's notion of discourse and Gramsci's sense of hegemony. Unlike Foucault, however, Said derives Orientalist discourse from master texts and canonical authors and thus misunderstands the Foucauldian approach to power (Bhabha, 1994: p. 72; Clifford, 1988: p. 265). Said also ignores the Marxist underpinnings of Gramsci's writing and fails to show how Orientalist discourse manipulates consent by real people in the Orient. Dennis Porter (1994: p. 152) notes that Said's Orientalism lacks "a sense of hegemony as process in concrete historical conjunctures, as an evolving sphere of superstructural conflict in which power relations are continually reasserted, challenged, modified."

Book-length summaries of the historical errors, rhetorical devices, and distortions in Said's *Orientalism* have been provided by Irwin (2006) and Varisco (2007). One of the most

common criticisms is Said's failure to include German-speaking Orientalists, who are among the most important scholars studying Islam and the Near East. Notably absent is the Hungarian-born Ignaz Goldziher (1850–1921), who is considered to be one of the major influences on the academic study of Islam in Europe (Patai, 1987). Said also ignores real Oriental scholars who responded to Western prejudice, including 'Abd a-Rahman al-Jabarti (1756–1825)' (Keddie, 1968). Arab critics generally dismissed Said's work, which ignores any critique written in Arabic. The Lebanese scholar Mahdi 'Amil (1985) provides a detailed rebuttal to Said's dismissal of Karl Marx as an Orientalist and rejection of all Marxist theory. Feminist scholars have noted Said's lack of engagement with female authors and the idea of the female racial other (Holmlund, 1993: p. 1).

Two egregious copying errors have drawn the attention of several critics. The first is a mistranslation of lines from Goethe's famous 1819 *Westöstlicher Diwan*. The phrase "Gottes ist der Orient!" is garbled by Said as "God is the Orient," but the German indicates the genitive. This is given by Said in a passage that blames Goethe for romantic pantheistic tendencies, but in this case Goethe was translating directly from the German translation of a Qur'anic verse (Surat al-Baqara 2:142), which reads "The East and the West are God's." A second example is a misquote of a passage Said uses to illustrate the anti-Oriental bias of Gustave Flaubert. Said (1979: p. 184) cites Flaubert as writing "Inscriptions and bird-droppings are the only two things in Egypt that give any indication of life" as an example of Flaubert's 'grotesque nastiness.' The actual text, both in the English translation cited by Said and in the original French, includes the words 'in the ruins of Egypt,' but Said does not provide an ellipsis for the missing words. Flaubert wrote this while visiting the monumental Colossus of Memnon, and it is clear from the French that the reference is not to hieroglyphic inscriptions but to travelers' graffiti. Such careless errors do not invalidate Said's overall thesis, but they indicate that his polemical interests outweighed his attention to sound scholarship.

Critiques of Orientalism before Edward Said

Although Said's *Orientalism* is the major English-language book to draw attention across disciplines and fields to bias in Orientalist writing, it was not the first demythologizing of the Orient concept. The most thorough study of the intellectual roots of the 'myth' of East vs West is Kurt Goldammer's (1962) *Der Mythus von Ost und West: Eine kultur und religionsgeschichtliche Betrachtung*. Targeted in this earlier study, not known by Said, is the tendency in the literature to ignore factual differences and to posit a false uniformity so as to reduce the East to a racial question and portray the East falsely as a mirror of the West. 'Das ganze Phänomen,' concludes Goldammer (1962: p. xx) "gehört zu der Unzahl von vorgefassten schematischen Meinungen und Begriffs-fixierungen, mit denen wir leben, unter denen wir leiden, die unseren Alltag und unsere Bildung erfüllen, und deren wir selbst nach generationslanger Abnutzung nicht überdrüssig werden" ("The entire phenomenon belongs to a large number of preconceived, schematic ideas and fixed notions with which we live and under which we suffer, that imbue our daily life and education, and which do not disgust us even after generations of use" (my translation)). Other pertinent criticisms of such an East–West binary were available, even in English. "Many a writer on Asia treats the Orient as though it were a single entity (which it is not) – and thus postulates a unity that has no real existence outside his own imagination," wrote John Steadman (1969: p. 14) a decade before *Orientalism* appeared. Arguing that there was "no objective basis for the dichotomy of East and West," Steadman proposed, in his study of the 'myth' of Asia, to provide "the anatomy of an illusion, the dissection of an eidolon." At almost the same time, Stephan Hay (1970: p. 30) went so far as to say that among scholars the "idea of 'the East' is now all but extinct." In 1973 the term Orientalism was abandoned at the 29th International Congress of Orientalists in 1973. The binary that Said rightly targeted for deconstruction was already under indictment by scholars within the very guild Said thought incapable of such self-critique.

Resources for Orientalism

There are several intellectual histories of the rise of Oriental studies, most now overshadowed by the polemical work of Edward Said. The major study through the middle of the twentieth century was Johann Fück's (1955) *Die Arabischen Studien in Europa* and Maxime Rodinson's (1991) *Europe and the Mystique of Islam*. These are now supplemented by Zachary Lockman's (2004) *Contending Visions of the Middle East*; Daniel Martin Varisco's (2007) *Reading Islam: Said and the Unsaid*; Ursula Wokoeck's (2009) *German Orientalism: The Study of the Middle East and Islam from 1800 to 1945*; and Ivan Kalmar's (2012) *Early Orientalism: Imagined Islam and the Notion of the Sublime Power*. Edward Said drew much of his historical information on Orientalists from Raymond Schwab's (1950) *La renaissance orientale*, published in English in 1984. For American Orientalism, two useful sources are Douglas Little's (2003) *American Orientalism: The United States and the Middle East since 1945* and Mari Yoshihara's (2003) *Embracing the East: White Women and American Orientalism*. A concise overview of Orientalism is given by Jacques Waardenburg (1992) in the second edition of the *Encyclopedia of Islam*. Oxford Bibliographies Online has an updatable bibliography devoted to Orientalism and Islam (Varisco, 2010).

Abstract

Edward Said's work on Orientalism gives meaning to social workers, particularly those interested in social work, which attends to issues of representation, power, privilege, and oppression. Both authors place Orientalism in context by examining social work discourse and practices associated with gender, anti-Arab racism and Islamophobia, Zionism, cultural competency, and international social work.

Orientalism in Context for Social Work

The word Orientalism predates Edward Said, but it was his analysis of the term combined with his determination to 'speak truth to power,' that has rendered the word transformative, contested, and revered. It is also his exploration of Orientalism that gives meaning to social workers. Attention to Orientalism can support social workers to understand common practices associated with helping 'others,' work across differences, and unpack normative professional narratives that inadvertently create knowers (i.e., social work professionals) and objectify 'others' (i.e., 'clients,' service users). For social workers addressing issues of social justice, Orientalism can provide insight into the dangers of objectification, mechanisms that create and maintain oppression and dominance – including ideas associated with neoimperialism – as well as the enduring nature of anti-Arab and anti-Muslim prejudice. Additionally, Orientalism provides social workers with a postcolonial lens that forces us to ask whose definition of social justice is being advanced and what is its relationship to dominance? As authors, one of us is a Palestinian-French Canadian with American citizenship, and the other a secular Jew who identifies as an ally to Palestinians, a framing of ourselves that constitutes the 'we' in this article.

Key Concepts in Orientalism

Edward Said's 'Orientalism'

As a Professor of English and Comparative Literature, Said's Orientalism was derived from his close readings of Anglo, French, and British post-Enlightenment literature as well as texts ranging from travelogues to political speeches. Although the geographical area explored by Said over the course of his 20 books was expansive, Arabs and Islam constituted his primary focus. The decision to focus on Arabs and Islam was based on both the historic position of the Orient and Said's own experience as an 'Oriental.' East and West are used to bifurcate the globe between Western parts of the globe, i.e., America, England, and Europe, and the exotic and less civilized East. Other terms like Global North and Global South are used to delineate industrialized nations from the nonindustrialized ones. In this article, East is used to represent both the geographic East and countries outside of the Western and industrialized hegemony.

Said was born in Palestine, schooled in Egypt, and worked in New York City. As an Oriental living in the West, Said both studied and experienced the themes raised in Orientalism, themes that included "racism, cultural stereotypes, political imperialism and dehumanizing ideology" (Said, 1992: p. 27).

What Is Meant by Orientalism

Prior to Said, Orientalism was an academic discipline dominated by Westerners who studied the near and far East. With the 1978 publication of his book *Orientalism*, Said shifted this subject of study. No longer was Orientalism a study of the Orient and its culture, rather it became the study of how the Orient is viewed, stereotyped, and thereby dominated by its opposite, the Occident, or the West.

The domination that Said spoke about included traditional colonization to what is presently considered neoimperialism. In the latter, former colonies are economically indebted to and controlled by the West through such entities as multinational corporations, international monetary structures, and even some forms of foreign aid in which the emphasis is on the security and economic interest of the donor agency rather than local need (Bayoumi and Rubin, 2000; Burney, 2012).

For a basic understanding of Orientalism, it is instructive to explore both the theories that underpinned Said's thinking as well as some of the stereotypes identified by Said. Said's Orientalism was influenced by the scholarship of French Psychoanalyst Jacques Lacan, French Philosopher Michel Foucault, and Italian Marxist Antonio Gramsci. Building on Lacan's notion of 'the gaze,' in which the objectification of another diminishes the object's autonomy, Said shifts the subject from the gaze on the Orient to the West's construction of the Orient (Bayoumi and Rubin, 2000). Said then locates Orientalism within Foucault's framework of discourse by arguing that the Orient is a creation of its binary, the Occident. In this binary, Occident is 'normative' and Orient is 'other.' Harkening to Foucault's work on knowledge production and its ability to manufacture 'truthful statements' about the subjects studied, Said argued that Western studies and its use of authoritative discourse created and then exploited a problematic view of the Orient. Gramsci's work on hegemony, as conceptualized by ideological leadership, allows Said to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28066-5

explain the enduring nature of Orientalism, even when faced with evidence to the contrary (Bayoumi and Rubin, 2000; Burney, 2012; Said, 1978).

Orientalist Stereotypes

Oriental stereotypes, according to Said (1978), are used to rob the Orient of its truths while both silencing and diminishing the Orient to the Occident. For example, Westerners celebrate Sir Edmund Hillary's achievement as the first man to conquer Mount Everest, despite evidence suggesting that Hillary's Nepalese Sherpa, who clearly carried the larger portion of the heavy lifting, most likely reached the top before Hillary. The example of Hillary and the Sherpa are repeated in many variations including Western geographic or archeological 'discoveries' of inhabited land.

In addition to stereotypes involving the Orient as a whole, Said spoke about the significance of several pervasive and self-reproducing stereotypes. These include Oriental depravity, Oriental splendor, and Oriental sensuality. Oriental depravity assumes many forms and a number of them are centered on the Prophet Mohammed, who is often vilified as an 'imposter.' Said explains that the label of imposter was the result of the incorrect assumption that Mohammed was to Islam what Christ was to Christianity, thus forcing Mohammed into a binary in which Christ was legitimate and Mohammed an imposter who needed to be destroyed or punished. Consider, for example, Dante's *Inferno* in which Mohammed's sin of deception places him with his entrails exposed in the eighth of the nine circles of hell.

As the Nepalese Sherpa is silenced, so are Oriental women who also do not speak for themselves. For example, consider Said's description of Flaubert's courtesan. She "never spoke for herself, she never represented her emotions, presence, or history. He spoke for and represented her" (Said, 1978: p. 72).

Oriental splendor and sensuality are iconic in figures such as Cleopatra, Salome, and Isis. While women such as Cleopatra conjure their own images, she is used in multiple other works (see for example, Charolette Bronte's *Villette*) to express the desires of nineteenth-century women. Additionally, images such as the Harem, as often depicted in nineteenth- and twentieth-century Orientalist paintings, shows both the exoticism and the depravity of the Orient. The Harem is often used in books and movies to illustrate splendor and depravity, and storylines tend to include a subtext of Western intervention. For example, it is often seen that the Western hero is often portrayed as seeking to save an Eastern woman or wandering Western women from the depravity and exoticism of the harem (Abdulhadi et al., 2011).

Orientalism and Representations of Arab and Muslim Women Post-9/11

There is relatively new literature exploring the post-9/11 depictions of Arab and Muslim women as found in the Western media and in policy debates. Given that Orientalized women do not speak for themselves, one of the major themes of the post-9/11 representations is the hyperoppressed, shrouded woman in need of Western intervention. This theme is beautifully expressed by Lila Abu-Lughod (2002) when she asked *Do Muslim Women Really Need Saving?* Abu-Lughod argues that in the post-9/11 world, depictions of Muslim women are largely essentialized as victims of 'the veil,' 'stoning,' and 'honor killing.'

While violence against women must never be condoned, images of hyperoppressed women have been used to justify war in Afghanistan, and distract from a broader analysis of global injustice. For example, in the case of Afghanistan, American constructions of Middle Eastern women as unable to speak for themselves reinforced Orientalist views, while 'women saving' supplied a liberal tilt to an unpopular war (Jarmakani, 2010: p. 228). For social workers committed to human rights, one can see how public support for Saudi women drivers or Afghani women's rights not to be fully covered serves as a distraction from systemic concerns associated with war, occupation, and colonization (Erakat, 2011). As different groups of Arab and Muslim women are seen as terrorized by Arab and Muslim men, their multiple and complex realities are simplified, essentialized, and appropriated by Western feminists (Abdulhadi et al., 2011) and their needs associated with national liberation, decolonization, freedom from racism, and poverty are erased and ignored.

For many Muslim and Arab women, wearing the veil is a choice that is associated with concepts of identity, personhood, religious and cultural beliefs, and esthetic preferences (Abdulhadi et al., 2011). Unfortunately, the relevance and reverence for traditions associated with wearing the veil for Arab and Muslim women are often obscured by stereotypes that lead to the pitying of them as the significance of the veil (to Westerners) is often misunderstood, and the agency of the women wearing it diminished.

Additionally, the Orientalized view of gender and gender oppression can distract social workers from engaging in any form of critical analysis of gender, religion, nationality, and ethnicity necessary for antioppressive practice. The Orientalized view of gender can lead to single and essentializing narratives such as Arab women are oppressed by their men, Muslim women have little agency in their day to day lives, and Arab women who wear hijab are oppressed. Antioppressive practice requires a critical analysis of power that includes attention to resistance, agency, and diversity across identities. There is no single story about Arab or Muslim women. Women, Arab and Muslim social workers, scholars, and activists find themselves responding to what Jarmakani (2010) calls false binaries such as whether the veil is oppressive or not, rather than the complex and lived experiences of patriarchy (because the question of gender oppression is not denied). In other words, efforts to support equality in gender and sexual orientation are interrupted as scholars' and activists' attention is turned from these issues to refuting Orientalist constructions of Muslim and Arab women by non-Muslims or non-Arabs.

Orientalism and the Persistence of Islamaphobia and Anti-Arab Racism

Written in 1530, and currently available in multiple stores, libraries, and on the Internet, the book entitled *Here after Foloweth a Lytell Treatyse Agaynst Mahumet and his Cursed Secte*

(Anon, 1530) speaks to the enduring nature of Orientalized depictions of depravity and the ways in which violence against Muslims has been justified. In 1978, Said wrote, that "practically the *only* ethnic group about whom in the west racial slurs are tolerated, even encouraged is the Arabs" (p. 26). Said's sentiment was affirmed 20 years later in 1999 in a widely cited report issued by the Runnymead Trust in England, indicating that anti-Muslim and anti-Arab discourse had become normative.

Today, the term Islamophobia is used to describe the racialized bigotry, and discriminatory policies and practices geared toward Muslims across the world, as well as to Arabs (and non-Arabs mistaken as Arabs) from a variety of religious backgrounds. Islamophobia and anti-Arab prejudice is particularly strong in Europe and the United States where Arabs and Muslims have been the target of discriminatory public policies, rising levels of intolerance, and hate crimes (Sayyid and Vakil, 2011). The vitriolic comments made by the North American woman who confessed to murdering Indian immigrant Sunando Sen in December 2011 are illustrative. She is quoted as saying "I pushed a Muslim off the train tracks because I hate Hindus and Muslims …. Ever since 2001 when they put down the Twin Towers, I've been beating them up" (Santora, 2012: p. A15).

For Muslims, Arabs, and individuals who are of Muslim or Arab decent or are perceived as such, living in the West includes many of the issues associated with being marked as racially and ethnically different. Difficulties include marginalization, racism, violence, isolation, and cultural imperialism. The resulting harms involve exclusion, stigma, hate speech and crimes, as well as stress including traumatic stress. Stereotypes of violence and terrorism accompany Muslim and Arab identities. In her exploration of Arab and Arab American youth living on the West coast of the United States, Naber (2012) interviewed youth in San Francisco who shared their disappointment and fear that the only portrayals of Arabs in the media are ones of Arabs as killers and radical terrorists.

While Orientalism helps place Islamophobia in context, social workers are faced with two important questions. What are the implications of Islamophobia and anti-Arab racism for social work practice? This question has particular significance given that social workers are often in the role of providing services to and working alongside Arab and Muslim individuals, communities, and colleagues. This question also has particular implications for social workers and social work students who identify as or are perceived to be Arab or Muslim. The second question, given our profession's commitment to social justice is what should be our role in addressing Islamophobia and anti-Arab or anti-Muslim prejudice?

Implications of Islamophobia and anti-Arab racism on social work practice include the need to incorporate Orientalism theory and content in social work education to attend to ethical standards that guide our profession, as well as to support antioppressive practice. This is suggested by the International Federation of Social Workers (2012), in Ethical Principle 4.2 – Social Justice – which identifies social workers' responsibility to challenge negative discrimination. Social workers cannot challenge Islamophobia or anti-Arab racism at micro-, mezzo-, or macrolevels if they cannot recognize either the phenomenon or their participation in it. Instead students, practitioners, researchers, and academics must understand the macroforces that have infused what individuals know about Arabs and Muslims and how they know it. Social workers must be able to unpack their own social identities, as well as how these inform their working relationships with diverse groups of Arabs and Muslims so that they can more effectively interrupt discrimination and oppression while working toward social justice.
